ABSTRACT

THE KOSHKONONG CREEK VILLAGE SITE (47JE0379): CERAMIC PRODUCTION, FUNCTION, AND DEPOSITION AT AN ONEOTA OCCUPATION IN SOUTHEASTERN WISCONSIN

by

Natalie Carpiaux

The University of Wisconsin-Milwaukee, 2018
Under the Supervision of Professor Robert J. Jeske

The ceramic assemblage recovered from excavations at the Koshkonong Creek Village (KCV) site (47JE0379) is examined to determine functional and stylistic significance from a temporal and spatial perspective. Occupied from circa A.D. 1000 to 4000, KCV presents an opportunity to look at Oneota in the locality from its early to late iterations. The ceramics were analyzed by attributes and categorized in a type-variety system laid out by Schneider (2015) for comparative purposes. Using a household approach and a feature-level analysis, ceramics trends are mapped and explored using GIS. The research collected lends credence to noted trends of cultural continuity in the locality, as well as some differences to be explored with future research. Results have implications for housing structures, the temporal use of ceramics, and shared ideology in the Koshkonong locality. While individual features and the excavated material recovered from each feature were not able to be directly tied to specific housing structures, the data still informs on domestic activity that occurred during the daily life of the Oneota household at KCV. Comparisons are made to other local sites, including Carcajou Point (47JE0002), Schmeling (47JE0833), and Crescent Bay Hunt Club (47JE0904).

ACKNOWLEDGEMENTS:

First and foremost, I would like to thank the Weisensel family, who have generously allowed for research at the Koshkonong Creek Village site located on their private property. Their continued support has enabled dozens of students to learn archaeological survey and excavation practices through the University of Wisconsin – Milwaukee field school. The subsequent research from the site, including this study, has resulted in multiple conference presentations, journal article submissions, theses, and dissertations.

Secondly, I would like to thank my advisor Dr. Robert Jeske and committee members Dr. Jean Hudson and Dr. Jason Sherman. Their guidance and varying perspectives aided in the interpretation of the data collected from this site. I would also like to thank Dr. Seth Schneider, who taught me everything there is to know about Oneota ceramics in the Koshkonong Locality. Dr. Schneider’s expertise was essential to understanding the assemblage at the Koshkonong Creek Village site. Special thanks are due to Dr. Richard W. Edwards IV, who’s knowledge of the site was invaluable. Dr. Edwards’s own research at the site was instrumental in interpreting results from my own analysis, and the assistance he provided with GIS mapping was vital to this study. I would also like to thank the friends and family who have been tolerant of my work schedule as I completed this research over the past few years. I could not have done this without the support of so many accommodating people.

Lastly, I’d like to thank the descendants of the Oneota, whose legacy was the subject of this research. What they have left behind has inspired scientific inquiry and will have a lasting impact on cultural heritage, indigenous lifeways, and the history of the region.
CHAPTER 1

Introduction and Background

The focus of this thesis is ceramic analysis designed to help understand community relationships and household activities of maize agriculturalists at the Oneota tradition Koshkonong Creek Village site (47JE0379) in the Koshkonong locality (Figure 1.1).

Oneota sites in the Koshkonong locality have been studied extensively since Hall’s seminal work on Carcajou Point in 1962. Since then, the University of Wisconsin – Milwaukee

Figure 1.1 Known sites in the Koshkonong Locality, adapted from Edwards (2010).
has done multiple surveys and field excavations from the 1970s onward (Jeske 2003a; Jeske et al. 2002; Musil 1987; Richards et al. 1998). Research has led to insights on intra-site and locality interaction, violence, and subsistence in the area, as well as re-defining timelines for early Oneota occupation dates in Wisconsin. What seems to be missing, however, is an understanding of the daily life and domestic activities of the people living in the villages in the Lake Koshkonong area. This study is an attempt to examine the social and domestic sphere of life in Oneota villages, and how ceramics can inform on worldviews, domestic activities, and social interaction.

Excavations at sites in the locality have uncovered numerous deep pit features, multiple differing housing structures (Edwards 2014; Edwards and Spott 2012; Gibbon 1968; Hall 1962; Jeske 2003a, 2010; Richards et al. 1998). Ceramics, floral and faunal remains, lithic tools, animal bone tools, copper artifacts, human remains and other data sets have been recovered from excavations over the past 20 years (Carpiaux and Edwards 2014; Edwards and Jeske 2017; Edwards and Pater 2011; Hall 1962; Jeske 2003a; Jeske and Edwards 2014; Jeske and Sterner-Miller; McTavish 2013; Milosavljevic et al. 2017; Musil 1987; Olsen 2003; Parkinson 2003, Pozza 2016; Richards et al. 1998; Schneider 2013; Schneider and Clauter 2007; Schneider et al. 2012; Wilson 2016). Interpretations of these pits and housing structures relies on spatial patterns and their contents (i.e., materials and artifacts recovered), which can in turn provide understanding of village layout, population, social dynamics, and lifeways of the Oneota in the Lake Koshkonong region.

This study will look to answer three questions about ceramics and their use at the site: 1) temporal changes in ceramics, 2) vessel function and possible activities, and 3) household size and interaction based on vessel size.
Oneota ceramics are often used to date sites and contexts by using temporally and geographically distinct phases. In the La Crosse locality, for example, multiple distinct phases including Valley View, Pammel Creek, and Brice Prairie have tight temporal ranges often spanning little more than a century. As a result, investigation into changing social dynamics, subsistence, ideologies, lifeways, and even trade and interaction can be discussed over time (Betts 2000; Bloedorn 2010; Boszhardt 1994, 2004, 2008; Gibbon 1995; Henning 1995; Overstreet 1995, 1997, 2000; Richards and Jeske 2002; Ritterbush 2006; Theler and Boszhardt 2003). In the Koshkonong locality, an understanding of ceramic phases is lacking. Certain vessel types defined in the area and decorative styles have been suggested (Hall 1962; Overstreet 1997; Richards and Jeske 2002), but have not been tied to a distinct phase. This lack of phases is due to significant intra and inter locality variation (see Schneider 2015). With dated ceramics and a spatial analysis, this study hopes to explore the possibility of dating specific types in the Koshkonong locality.

Vessel function is a way to explore the domestic activities of daily life in an Oneota village in the Koshkonong locality. Function can be determined by shape of the vessel, manufacturing techniques, and use-wear (Briggs 2016; Feathers 2006; Hawsey 2015; Kooiman 2016; Rye 1976; Schiffer et al. 1994; Skibo 1992). By examining function, and additional lines of evidence, an understanding certain domestic activities may become apparent (Carpiaux and Edwards 2017; Crown et al. 2012; Kooiman 2016; Miller 2015; Upton et al. 2015)

Larger volume ceramics imply larger amounts of food being cooked, served, and stored. This may be due to feasting, pooling of resources, or other food sharing activities. Ceramics have also been used on multiple occasions to determine household sizes or even as proxies for population (Betts 2006; Blitz 1993; Frankel and Webb 2001; Kooiman 2016). By understanding
household sizes and village populations, we gain a better understanding of subsistence needs and inter and intra-site cooperation, and thus aiding in future research and interpretations of sites in the Koshkonong locality.

This research aims not only to improve understanding of village life at KCV though the ceramic assemblage, but to aid in future interpretations of the sites in the area. While extensive knowledge about tools, trade, subsistence, and violence are being explored in the locality, village daily life is still lacking. With this study as a foundation, future research and additional lines of evidence may build upon the understanding of the sites themselves and the people who lived there hundreds of years ago.

Chapter One of this study discusses Oneota background and previous research in the Koshkonong locality. It also explores additional research done in other Oneota localities. Chapter Two looks at the theoretical framework of household archaeology and its applications, and how it will aid in understanding research from the data collected in this study. Methods and expectations are explained in Chapter Three, while the data collected during the ceramic analysis is laid out in Chapter Four. Finally, interpretation and discussion of the data occur in Chapter Five.

**Oneota Background:**

Oneota is a term used to describe material culture, particularly ceramics, used by people who shared a generally similar set of subsistence, settlement and technological practices distributed across the prehistoric northern Midwest (Alex 2002; Griffin 1937; Hall 1960; Henning 1998; Overstreet 2000). Distribution of the Oneota tradition is manifested in sites across the northern Midwest, such as Illinois, Iowa, Minnesota, Wisconsin, South Dakota,
Nebraska, and Kansas (Henning 1998; Ritterbush 2006), but Oneota ceramics have been identified “as far east as Michigan and Ohio, west across the Central Plains, south into Oklahoma and north into Ontario and Manitoba” (Staeck 1995:4). According to Benn (1989), Oneota society was based on tribal organization, and did not display the same complex social patterns of Mississippian groups in Cahokia or the American Bottom. In southeastern Wisconsin, however, Overstreet has indicated “profound cultural complexity” in regards to settlement, subsistence, and interaction (2000:429). Ethnohistoric and mortuary evidence suggests relatively egalitarian society with occasional achieved individual status, and clan ties to upper and lower world animal totems (Benn 1989; Foley Winkler 2011; Schneider 2015).

However, these general patterns vary widely across the Midwest, with local variations such as at Lake Koshkonong showing significant divergence from the norm (Benn 1995; Brown 1990; Edwards and Jeske 2015; Foley Winkler 2011; Gibbon 1972; Henning 1995; Jeske 2003b; Jeske et al. 2016; Overstreet 1997; Schneider 2015; Wedel 1959). Depending on how one defines the term Oneota, Oneota sites date between A.D. 1050 – 1650 A.D, with earlier dates in northeastern Illinois and eastern Wisconsin, and later dates in northeastern Illinois, western Wisconsin, and Iowa (Boszhardt 2004; Jeske 2008; Overstreet 2001). In eastern Wisconsin and northeastern Illinois, it appears that Oneota groups were maize agriculturalists who also relied on hunting and gathering of a wide variety of wild terrestrial, avian, and aquatic resources (Edwards 2017b). Oneota village sites were generally semi-permanent or permanent habitations situated near lakes, rivers, and agricultural land (Edwards 2010; Hall 1962; Overstreet 1997). Dwellings vary from small nuclear family buildings to large longhouses accommodating the extended family or multiple families. Tools include lithics, modified faunal remains, copper, and ceramics
Previous research suggests village and locality interaction among Oneota due to shared artifacts, ideologies, and lifeways. Items like catlinite pipes or trade copper and similarities in ceramic and rock art motifs suggest shared socio-political significance and interaction (Benn 1989; Theler and Boszhardt 2003; Schneider 2015). Despite widespread identification of Oneota sites across the upper Midwest, the Oneota in the Koshkonong locality demonstrate significant variation from other localities. Previous research (Edwards and Jeske 2015; Jeske et al. 2016) has indicated a unique pattern of subsistence, cultural material, and political and economic relationships to other Oneota localities. Because of these noted differences, interpretations from other localities may not be suitable as analogies for the daily activities and social dynamics within the village. Thus, interpretations at KCV must rely more heavily on conclusions from local sites such as Crescent Bay Hunt Club (CBHC) or Carcajou Point.

Subsistence:

Subsistence at Oneota settlements is considered diverse, making use of local natural resources and good agricultural soils for horticulture (King 1993). Oneota subsistence, referred to as an adaptive strategy by Rodell (1983), included agriculture and the exploitation of wetland, riverine, or lacustrine environments (Edwards 2010; Richards and Jeske 2002; Schneider 2015). Flexible exploitation of varying environments helped provide a diverse diet for growing populations. Villages are placed strategically to make use of fertile soils and for proper drainage. Ridged field complexes, theorized to aid in drainage are found in Western and Northern Wisconsin, suggesting large-scale community coordination in the building and maintenance of...
the agricultural system (Boszhardt et al. 1985; Bruhy 2015; Edwards 2010; Edwards 2017a; King 1993; Olsen 2003). Ridged fields are known from Eastern Wisconsin and the Koshkonong locality, but connections to Oneota groups is unclear.

Agricultural crops grown included squash, maize, and beans (Overstreet 1997). Archaeobotanical research suggests maize was an important staple for Oneota groups (Edwards 2017a; Edwards and Jeske 2017; Olsen 2003). In the Koshkonong locality, high row maize found in high density suggests a continuation of subsistence strategy shared by Late Woodland groups in the area (Egan-Bruhy 2014; Picard 2013). Dental carries, often a sign of maize-heavy diets, found on Oneota remains support this. Despite common finds of skeletal stress at Oneota sites, Tubbs and O’Gorman (2005) argue these bioarchaeological markers of stress are not due to malnutrition, but infectious disease or parasites caused by changes in domestic arrangements due to increased sedentism and population growth. They argue Oneota diet was nutritionally sufficient, and that it was “remarkably rich” (2005:152). This richness may or may not be the case for Oneota in the Koshkonong locality, however, as evidence of nutritional stress have been noted in skeletal remains (Foley Winkler 2011).

Wild plant foods were also utilized, including seeds, nuts, fruits, and wild rice. A variety of crops and plant foods such as nuts and seeds ensures nutritional security, as a bad crop yield could create nutritional stress (Olsen 2003). According to Edwards (2017a), Oneota in the Koshkonong region relied heavily on maize, but supplemented their diet with nuts and wild rice. Archaeobotanical evidence demonstrates the incidence of nuts declines at Oneota sites over time, while use of wild rice grows and continues to remain an important supplementary food source. According to Jenks, much of Wisconsin and northern Minnesota are known as the “Wild Rice District,” in which wild rice grows abundantly and was an important staple for native groups
Wild rice threshing pits found at the CBHC site support this notion of wild rice as an important Oneota staple (Moss 2010; Olsen 2003). Along with wild rice and maize, faunal and floral analysis of features excavated from CBHC suggests that chenopodium, fish, and wild game mammals were a significant portion of the Oneota diet in the Koshkonong locality (Edwards and Pater 2011). Slight changes in macrobotanical evidence over time suggests that during early occupation in the locality, Oneota supplemented their agricultural yields with wild foods, and relied more heavily on domestic crops as time progressed. Edwards (2017b) suggests this increase in cultivated foods may be due to deforestation and potentially increasing violence in the area, preventing extensive hunting and foraging trips.

The use of mussel shells in ceramics are an identifying feature of Oneota sites (Alex 2002; Behm 2007; Boszhardt 2008; Overstreet 1997). Mussels, though relatively low in nutritional value, can be collected, dried, and stored in large numbers, and make for a suitable nutritional supplement during winter (Theler 1987). Despite their low nutritional value, we know mussels were being utilized in the Koshkonong region due to cooked shells found in middens and the use of crushed mussel shells in the ceramics (McTavish 2013).

*Oneota Ceramics:*

According to Rice (1987:245), archaeologists use pottery style to reconstruct the “histories and cultural relation of peoples who occupied archaeological sites.” This use is especially true of Oneota sites, as Overstreet (1997:251) states ceramics are the most definitive way to identify an Oneota settlement. Variations in Oneota ceramic styles have also been used to identify regional development or phases and Horizons (Hall 1962; King 1993; Schneider 2015; Overstreet 1976, 1981, 1997; Theler and Boszhardt 2003; Tiffany 1997).
Traditionally, specific styles in different localities were thought to have been found to be associated with specific time periods, allowing researchers to date contexts based on ceramics recovered at the site. In the literature, the Oneota tradition has been divided into a number of horizons: Emergent (A.D. 950 – 1150), Developmental (A.D. 1150 – 1350), Classic (A.D. 1350 – 1650), and Historic (post A.D. 1650) horizons (e.g. Overstreet 2000). Recent research has shown that there is enough regional variation in chronology and ceramic types that the horizon concept has little utility (Edwards 2010; Foley Winkler 2011; Jeske 2008). Schneider (2015:6) states that, “Given the uncertainties surrounding chronology and regionalism, it is more realistic to discuss sites in terms of their chronological and regional locations until a clearer picture of the interregional relationships among sites appears.”

The typical Oneota vessel (Figure 1.2) is a shell-tempered, globular jar with rounded shoulders and a flared rim, with decoration usually concentrated around the vessel shoulders (Behm 2007; Boszhardt 2008; Brown and Asch 1990; Hall 1962; Overstreet 1997; Richards and Jeske 2002; Schneider 2012, 2015). They are manufactured by hand, low-fired, and produced at the household level. Hall’s (1962) excavations at Carcajou Point is often seen as the seminal work on Wisconsin Oneota ceramics, being one of the earliest and most descriptive in the area. He notes many similarities to the standard Oneota vessel, including rounded shoulders at 77% of the assemblage, but angled shoulders were also recovered (1962:56). Hall also found a high variation in rim height and thickness, and few bowls. Handles found were rare, and often of the loop variety, with only one instance of a lug handle. Suspension holes were also found on occasion. The categories described by Hall were the standard for many years until Schneider (2015) re-organized vessel types.
Although the overwhelming majority of Oneota vessel forms are olla jars, other ceramic vessel forms found at Oneota sites include miniature vessels, bowls, beakers, and bottles, while other ceramic artifacts include pans, spoons/ladles, cut sherd disks, and clay pipes (Arzigian et al. 1994; Berres 1998; Hall 1962; Schneider 2015). Bowls are typically rare in Oneota assemblages, as many serving dishes were likely made of wood (Wilson 1917) and thus unlikely to be recovered in an archaeological context. Catlinite disk pipes are common at Oneota sites (Overstreet 1997; Painter 2014; Sasso 1989), as are clay elbow pipes such as those recovered at Carcajou Point (Hall 1962) and at CBHC and KCV (Jeske et al. 2017).
The globular jar shape of Mississippian and Oneota vessels is generally accepted as a cooking pot. It is postulated that the shape is a multi-use utilitarian tool, which is designed for thermal shock resistance and ideal for long cooking times (Berres 1998; Hawsey 2015; Briggs 2016), as well as serving for non-cooking activities such as storage, transport, or processing. Shell-tempering was even theorized to aid in the nixtamalization of maize (Morse and Morse 1983; Myers 2006). However, Upton et al. (2015) suggests this theory to be questionable and that wood ash lye was more likely utilized. Oneota staples, such as maize and wild rice, require long-term boiling and processing to render it edible (Briggs 2016; Wilson 1917). Thus the globular cooking jar is a perfect adaptation to this subsistence strategy. The shape of the vessel, and use-wear often found on Oneota vessels, indicate the rounded bottom was often placed directly over a bed of coals for cooking purposes (Boszhardt 2008).

Oneota Settlements:

Housing structures identified in Oneota villages include longhouses, pit houses, and pole-frame houses similar to wigwams (Edwards and Spott 2012; Hall 1962; Moss 2010; Overstreet 1976). All of these housing types have been found in the Koshkonong locality (Figure 1.3). Even though every archaeological structure is not a house, a study by Alexander (2013) found the structures in the La Crosse locality to be mostly domestic in function. Some ceremonial function may be applied to longhouses with burials, but ceremonial evidence was limited. Longhouse structure at Oneota sites describes benches along the edges of the structure, with a fireplace in the center. Archaeobotanical research in the Koshkonong suggests otherwise, with evidence of longhouses being communal or ceremonial in nature (Edwards 2017a). While the longhouse appears to be utilized as a domestic living space in the La Crosse locality during later occupation
periods (O’Gorman 2010) dates obtained from features associated with longhouses at CBHC indicate the housing styles was used much earlier in the Koshkonong locality (Moss 2010).

Oneota post-martial residence is not yet fully understood, but there have been studies suggesting it may have changed over time. Based on floor sizes, Hollinger (1995) suggests that

Figure 1.3 Differing housing structures in the Koshkonong Locality, including a pole-frame house identified at Crescent Bay (top right, Gibbon 1968), a trench house identified at Carcajou Point (top left, Hall 1962), and a longhouse identified at Crescent Bay (bottom, Moss 2010).
Emergent and Developmental housing structures were patrilocal in post-marital residence. Classic horizon structures, he elaborates, fit the floor area size of matrilocal residences, suggesting a change in social structure or ideology. Other reasons suggested for the shift from smaller housing structures to larger ones include violence and warfare, solidarity and community strengthening (O’Gorman 2010), and summer vs. winter occupation. In the Koshkonong region, however, evidence of the longhouse being utilized pre-1400 suggests housing patterns, and sociocultural explanations for these patterns, likely differ from other localities (Jeske 2010; Moss 2010).

Large storage pits, seen in basin, cylindrical (Figure 1.4), and bell-shaped forms, are another common feature of Oneota villages (Alex 2002; Bruhy 2015; Sasso 1989). Other than storage, pits found at sites have been designated for other use such as rice-threshing pits and

![Image: Deep cylindrical basin (Feature 12-06) at KCV.](image-url)
hearth (Jeske 2003a). An experimental study in subterranean storage pits showed viability of seeds stored over winter to germinate the following spring, and excellent protection from fungus growth and infestation (Martinek 1998). The original function of these pits are often not the context in which they are excavated, as they are often re-used for refuse disposal (Carpiaux and Edwards 2017; Richards et al. 1998).

Interment of the dead for Oneota varies by locality. In the Koshkonong locality, multiple forms of interment have been noted, including burial in formal cemeteries, under housing structures, the edge of sites, or in refuse pits as full burials and isolated partial remains (Edwards and Jeske 2015; Foley Winkler 2011; Jeske 2014; Jeske and Edwards 2014; Jeske and Sterner-Miller 2014). Mound burial and formal cemeteries have been noted in the Grand River Locality (Foley Winkler 2011; Jeske 1927). In the La Crosse Terrace, mortuary patterns include mounds (both primary and intrusive), burial clusters in village settings, and under housing structures, and have been discovered as single isolated burials, familial groupings, or secondary burials (Arzigian et al. 1994; Hollinger 1993; O’Gorman 2010; Sasso 1989).

**Site Background:**

The first to document the archaeological sites in the Lake Koshkonong region (Figure 1.1) was Increase A. Lapham. According to Lapham, the Lake Koshkonong area was “abundantly supplied with means of subsistence” and evidence of numerous examples of native occupation were documented in the area (Lapham 2001 [1855]:35). Because of these abundant resources, the area has been occupied for at least 12,000 years (Jeske et al. 2002; Winkler and Jeske 2003). The well-drained, loamy soils have supported agricultural use from Oneota occupation to modern times (Edwards 2010; Musil 1987). Stout and Skavlem (1908)
documented sites along Lake Koshkonong, including CBHC and KCV, describing clusters of artifacts and mapping several mounds in the area.

Research on Oneota sites in the Koshkonong locality has been based on the excavations and survey at the CBHC, Schmeling, Carcajou Point, and Crabapple Point sites (Figure 1.1) and have resulted in numerous theses, dissertations, presentations, and publications expanding on the understanding of the sites, subsistence, social interactions, and material culture in the Koshkonong locality (Carpiaux 2015, 2017; Carpiaux and Edwards 2014, 2017; Edwards 2010, 2014, 2017a, 2017b; Edwards and Jeske 2015, 2017; Edwards and Pater 2011; Edwards and Spott 2012; Foley Winkler 2011; Hall 1962; Jeske 2003a, 2008, 2010, 2014; Jeske and Edwards 2014; Jeske et al. 2016; Jeske and Sterner-Miller 2014; Jeske et al. 2017; Jeske et al. 2002; McTavish 2013; Milosavljevic et al. 2017; Moss 2010; Musil 1987; Olsen 2003; Parkinson 2003; Pozza 2016; Richards and Jeske 2002; Richards et al. 1998; Schneider 2012, 2013, 2014, 2015; Schneider and Clauter 2007; Schneider et al. 2012; Spector 1975; Sterner 2011; Sterner and Jeske 2017; Wilson 2016; Winkler and Jeske 2003). These sites are within close proximity to the lake, making use of the aquatic resources and vast wetlands. Research has indicated the Koshkonong locality as unique in the Oneota cultural landscape. It is more isolated, with approximately 70 km separating it from other surrounding localities (Edwards and Jeske 2015). Evidence of violence (Jeske 2014) at the site and nearby Aztalan is a potential motivation for this isolation.

Modern development and farming has affected the environment and archaeological sites. Dams and land development, increased game hunters, and farmers settling in the area further changed the landscape and its uses (Musil 1987). Sites destroyed by construction and deep modern plows may limit our understanding of the area and its former occupants. This is
evidenced by early surveys of the area. Early surveys of the area, including what is now known to be CBHC, noted large depressions on the surface. These were interpreted by Stout and Skavlem (1908:80-81) as cache pits and wild rice threshing pits. Evidence of pits still open, even potentially 700 years after their original construction, affects how these excavated features can be interpreted. The original use of these pits as storage or cache pits and rice threshing pits is supported by ethnographic research (Jenks 1900; Wilson 1917). The excavated remains of these former storage or threshing pits has captured its final use; after the pit has been abandoned and subsequently re-used as a refuse pit. Thus, association of pit features with housing structures can only be made for the initial uses, and not their excavated context. The surface depressions Stout and Skavlem (1908) noted in the early 1900s have long since been obscured by decades of farming and land use.

Ceramic research in the locality indicates a cultural continuity among sites. Local trends, such as Busseyville grooved paddle vessels, have been found at KCV and continue to verify its ties to the locality (Carpiaux and Edwards 2014, 2017; Schneider 2012). Schneider et. al (2012) showed that the potters at KCV occasionally used a different clay source from CBHC and the Schmeling sites. Some pottery was found to be similar clay source though, suggesting potential trade or interaction between groups living at the sites, or that potters at KCV traveled farther to acquire clay.

*Koshkonong Creek Village:*

KCV is located just over two kilometers north of the lake in Busseyville, and is situated on the Weisensel family farm, which has been actively cultivated for over a century. Most of the artifact clusters indicate the village was situated in the bounds of the current cultivated fields,
with a Woodland occupation closer to the edge of the site, located near a bluff overlooking Koshkonong Creek (Edwards 2010; Edwards and Spott 2012; Musil 1987). At the time, the area was oak savanna (Edwards 2010). The location and environment of KCV is essential to understanding the unique subsistence adaptations from other Oneota sites in the locality. With the creek comes access to wetland and aquatic resources, but the oak savannah and arable land on which the village is situated provides a wide range of resources for which the site inhabitants can take advantage of.

KCV was initially interpreted as a village from Stout and Skavlem’s 1908 site description and Charles Brown’s (1909) notation of mounds and village material known as the Koshkonong Creek site. In 1986, UW-Milwaukee’s Southeast Wisconsin Archaeological Project (SEWAP) returned, completing a pedestrian survey of the site area, and renamed the village the Twin Knolls site. Both an Oneota and Late Woodland occupation were recorded and a total of 3024 items were collected, including lithics, ceramics, floral and faunal remains, and copper implements (Musil 1987). UWM returned to the site in 2008 to conduct a walkover survey and re-map the site. Subsequent work on the site has used the name Koshkonong Creek Village (Edwards 2010).

**UW-Milwaukee Field School Excavations:**

During the 2010 field season, a small-scale excavation of the Late Woodland occupation near the creek bluff was conducted. Investigation of the Oneota component was the aim of excavation during the 2012 field season at KCV. Based on artifact densities from 2008 and 2010 pedestrian surveys, the description of artifact distribution in Musil (1987) (Figure 1.5), as well as spatial and artifact information provided from the Weisensel family and Mr. Kevin Schmeling (a
local neighboring farmer and collector), the densest artifact distribution centered approximately 100 meters north of the modern farmhouse and 30 meters west of the present farm road (Edwards

Figure 1.5 Artifact concentration at KCV from walkover survey (Musil 1987).
Figure 1.6 University of Wisconsin-Milwaukee field school excavations, including the Late Woodland occupation excavations in 2010 (top red square) and subsequent Oneota excavations (bottom red square).
A ten meter by four meter excavation block, divided into ten total two by two meter units was laid out within this area of high artifact density (Figure 1.6). A total of 40 square meters were excavated during this season.

Excavation began by removing the plow zone, which averaged 25 cm deep across the excavation block. Following removal of the plow zone, each unit was mapped and features identified at the subsoil level. It was this point that features were assigned numbers. Some plow scarring was still visible at the subsoil, so these areas were mapped at the top of this level. Features were then bisected by a trench to be profiled, and the remainder of the feature (known as feature fill) collected as flotation samples. Soil excavated from the trench, or feature trench fill, was screened with ¼ inch mesh. Any stratigraphic zones were identified based on color or texture change; they were included in the map and excavated separately. Several of the largest features showed multiple zones, some of which had unique artifact densities from the rest of the feature.

The 2012 field season revealed a total of 48 features within the excavation block, including 37 post molds, four basins, two cylindrical pits, two shallow basins, one wall trench, one hearth, and what was either a large post or a small pit. One feature was left unexcavated because it extended under the back dirt pile and could not be easily accessed. Positioning of posts lead to the identification of at least one structure, and possibly another, within the excavation block. The structures may be similar in size and shape to the longhouses seen at CBHC (Moss 2010) or the rectangular house described at Carcajou Point (Hall 1962). Since the entire structure was not exposed during the excavation, neither style can be definitively verified.
Features 12-02 and 12-05 were both shallow basins measuring approximately 50 cm in diameter. Both were less than 6 cm deep from the bottom of the plow zone, and the upper section of these pits were likely disturbed from agricultural activity. Features 12-04, 12-26, and 12-32 were basins with a high density of artifacts. These basins were approximately 15 cm deep.

Features 12-01 and 12-06 were deep cylindrical pits, both extended over a meter into the subsoil and were approximately a meter in diameter. These features showed evidence of distinct zones, which may have been episodes of mass disposal. Lenses of ash, fish bones and scales, and general cultural deposits were mapped in the feature profiles (Edwards and Spott 2012). All of the pit features were interpreted as refuse or middens, most likely post-use from another purpose. While the basins may have originally constructed as storage pits, similar cylindrical pits had been interpreted at CBHC as rice-threshing pits (Moss 2010). Further archaeobotanical and faunal analysis of the features may help with the interpretation of the features and subsequent inferences of daily domestic activities (Fuller et al. 2014).

The 2014 field school attempted to expand on the 2012 excavation, and was placed in hopes of catching additional walls from the previously identified structures (Figure 1.7). The 2014 units were placed southeast of the 2012 excavation block. During this season, the excavation block was expanded by a half meter, making the entire block ten meters by 4.5 meters and spanning 45 square meters total. Ten units were placed along the outside edges of the block, with a .5 by ten meter baulk running down the center separating units along the east and west sides of the block. The plow zone was removed by screening the southwest quadrant of each unit with ¼ inch mesh, while the remaining quadrants were removed without screening.

Over 60 post molds and 16 pit features were uncovered in the 2014 excavation block (Edwards 2014). The pit features included three shallow basins, six basins, five cylindrical pits,
and two pits that were left unexcavated. Regardless of its earlier function, each pit has been interpreted as being re-used as a midden, turning up the same kinds of village refuse found in the 2012 pits. Three of the pits were also found to have isolated human remains, which have since been reburied at the site. The cylindrical pits were approximately 1.5 meters in diameter and extended approximately a meter below the plow zone. Much like the 2012 season, it seemed that the upper levels of many of the pits were damaged through agricultural cultivation, and were much shallower than they had been during prehistoric use. As in the 2012 season, some of the larger features, such as Features 14-05 and 14-18, had distinct stratigraphic zones which were noted during excavation. Overlapping features may have been the result of re-use at the site but,
Figure 1.8 Oneota excavations at KCV from 2012, 2014, 2016, and 2017, including potential structures based on post holes.
given that many of the overlapping features were not of the same depth, these overlaps may have served as step-downs into the larger features.

Like in the 2012 field season, the features in 2014 were bisected with a trench and profiled before the remainder of the features were excavated. While feature material that was not part of the trench was initially supposed to be removed as flotation samples, the sheer amount of soil to be removed made this impractical. Thus, alternating flotation samples and screening with ¼ inch mesh was utilized to finish excavations in the feature fill section.

Additional excavations since this study was completed in 2016 and 2017 have expanded understanding of the site layout (Figure 1.8). A small scale excavation in 2016 recovered relatively little material, but did expose post-holes indicating a corner of a structure. Field school excavations in 2017 revealed multiple post-hole arrangements suggesting structure re-building episodes. Current plans to re-survey the excavated area using ground penetrating radar will help aid with site interpretation, as current maps indicate possible skewed spatial data.

Dates:

Despite reservations toward early dates obtained from Oneota sites in the Koshkonong locality and the surrounding debate (Boszhardt 1994, 1998, 2004; Richards and Jeske 2002; Richards et al. 1998; Hall 2004; Overstreet 1976, 1998, 2001), there is mounting evidence of early Oneota occupation in the area as additional dates are obtained and calibration becomes more precise. With multiple dates of circa AD 1000 – 1100, the sites in the Koshkonong locality pre-date La Crosse and Iowa Oneota occupations.

Over twenty radiocarbon dates have been obtained from sites excavated from multiple seasons of the University of Wisconsin-Milwaukee field school (Figure 1.9). The dates here are
Figure 1.9 Radiocarbon dates from the field school excavations at CBHC, KCV, and Schmeling sites.
based on samples from annual plant matter and ceramic residue. They indicate occupation in the area between AD 1050 – 1450. To this date, KCV has five radiocarbon dates from the residue of four ceramic vessels and one botanical sample.

Dated ceramics were obtained from carbonized residue on the interior of vessels (Figure 1.10). Interior residue was relatively infrequent, and most residue was noted on the exterior of vessels, particularly below the rim. The dated ceramics include two Grand River vessels, one Busseyville vessel, and the only Calumetville vessel (Vessel 120) identified in the assemblage.

The following are all two-sigma calibrated dates. The two Grand River Vessels indicate that the type was used for the entire site's occupation. One vessel dates to A.D. 990 – 1145 and the second ranges from A.D. 1296 – 1403. The Busseyville vessel has a similar date range as the later Grand River vessel at A.D. 1300 – 1405. The Calumetville vessel date range is between A.D. 1225 – 1290. This date range is similar to that of the Schrage site, where the Calumetville type was first identified (Schneider and Richards 2010).

![Figure 1.10 Residue on interior of lip from Vessel 120, recovered from Feature 14-29.](image)
These dates have some interesting implications. Grand River vessels span the entire occupation of the site, with the earliest and latest two-sigma ranges. These were taken from Features 12-01 and 12-06, respectively. Interestingly, an additional date was obtained from a bean (*Phaseolus vulgaris*) in Feature 12-06, dating even later with a two-sigma range of A.D. 1400 – 1440 (Figure 1.11). There is some overlap in these ranges, suggesting that Feature 12-06 dates approximately toward the end of known occupation at the site.

While the Busseyville vessel dates to a similar range as the later Grand River vessel in 12-06, the Calumetville vessel dates closer to the mid-range of the occupation. The two-sigma ranges are very close, suggesting the feature may date closer to A.D. 1300. Another reason for the difference in dates may be vertical distribution of the vessels within the feature itself. Unlike the Busseyville vessel, the Calumetville vessel was found near the top of Feature 14-29. Bioturbation and subsequent use of the land after disposal of the vessel within the pit likely affected the recovery location of the sherd.

**Figure 1.11 Digital profile of distinct zones in Feature 12-06, highlighting the location in which dated material was recovered.**
CHAPTER 2

Theory of Household Archaeology

Blanton describes the household as a “group of people coresiding in a dwelling or residential compound” and “share householding activities and decision making” (1994:5). But to understand the implications of relationships and activities within the household, this definition may be too simplistic. Household archaeology requires the perspective of looking at the household as a unit in terms of production, consumption, pooling of resources, reproduction, co-residence, and shared ownership (Ashmore and Wilk 1988, as cited in Rodgers 1995). According to Wilk and Rathje (1982:4-5), “Archaeologists do not excavate households; they find the material remains of dwellings. The household itself is a unit of economic and social cooperation that does not necessarily live under a single roof, though often it does.”

A fundamental part of studying households is defining them, and the literature has a wide range of definitions. Rodgers (1995) explains the household as an economic, biological and social unit that interacts with others through a constantly changing set of relations. He also says form and function of the household is essential to its understanding. The form of the household is its social and kinship relations, while the function is the range of activities in which household members participate (1995:8).

Hendon (1996) states that household archaeological investigations are essentially research on the domestic group, and are useful in feminist and economic archaeology. Studies on food processing, foods eaten, and social responsibility of domestic activity is based on ethnographic sources as a comparison to archaeological materials. According to Rogers, household archaeology encompasses multiple themes, including “spatial, social, population or

Households are the smallest scale for investigating domestic remains (Nash 2009). Thus, households become an avenue for discussing the needs of economic partners within the broader community. As sedentism and agricultural activity increases, the household becomes the basic social unit within a community (Byrd 2000). Byrd noted that in southwest Asia, early agricultural communities result in restriction of social networks for sharing, production, and consumption. This changes the household’s relationship to the community as a whole. Individual needs may be difficult or impossible to parse out archaeologically, but households can be spatially defined in an archaeological setting, and be used to infer community needs and social interaction on domestic activity.

While fully understanding the potential of household perspective on material finds can provide avenues for interpretation, it is important to understand the limitations as well. Hendon argues that household archaeology should not be “a convenient justification for the excavation of houses” but should explore what households do and why the household matters (1996:55). Meaningful comparisons can be made using the household as a unit, but objective data collection is a must. “Many archaeologists know they are digging in houses, but they do not excavate them as houses. They instead dig them as if they were homogenous containers” (Nash 2009:205-206).

Ames suggests that household theory needs to be developed to understand the function of the household and how the household affected groups culturally and evolutionarily (2006). There seems to be a general consensus among household researchers that household theory is undeveloped and there is great potential to inform on many social aspects of community organization (Ames 2006; Hendon 1996; Nash 2009), however, the over-application and assumption of social ties in relation to inferred households is important to be aware of (Wilk and
Rathje 1982).

Household Archaeology and Ceramics:

Gendered analyses of ceramic technology are becoming increasingly common, as studies have shown women’s involvement in the “invention and production of fired clay containers because of their role in food preparation” (Hendon 1996:51). Even Benn (1989), who discussed ceramic motifs and iconography from a distinctly male-oriented point of view, later (e.g., Benn 1995) indicated that this perspective was biased, considering the gendered roles regarding ceramic technology. With women as an integral part of the domestic realm, household analysis brings women’s lives and roles more prominently into our picture of the past. But even if ceramic production is not dominated by women, such as instances of specialized mass production, the use of pots in the domestic sphere (the household) can still be tied to women’s roles. However, other approaches to household archaeology and ceramics are common.

For example, Frankel and Webb (2001) looked at regional pottery use, consumption, and discard to understand settlement size, structure, and population at a Bronze Age site in Cyprus. Their use of population, based on cemetery data, and ceramic discard gave an approximate number of vessels discarded per year, and thus the number of vessels needed for replacement each year. Household size was determined by habitable space of housing structures. They were able to discuss possible production methods, such as small-scale regional specialization versus individual household production. The production method of pottery at this ancient site would have impacts on how households interacted and cooperated. It has also been suggested that ceramics might be used to determine post-marital residence (Deetz 1965; Hill 1970; Longacre 1968; Overstreet 1978), but there is still disagreement on the effectiveness of this type of study.
(Hollinger 1993; Rodell 1983).

Other studies have used pottery to discern populations, feasting, and household sizes. A study by Blitz (1993) compared vessels from Lubbab Creek, a mound and village site in Pickens County, Alabama about 55 km west of Moundville. Assemblages from the mound and village contexts were comparable in shape and decoration, but size was not. A larger proportion of larger-sized vessels were found in association with the mound, suggesting feasting and large-scale food preparation. Feasting contexts had less variety in vessel size, while a domestic context usually displayed a variety of vessel sizes for different cooking and household needs. Betts (2006) utilized pot size in the La Crosse locality to determine population. Neck diameter was used to approximate vessel volume, and found that over time, increased vessel size indicated an increase in population in the area. A study by Kooiman (2016) utilized use-alteration, residue, and carbonization patterns to look at vessel function. She found that vessel size appeared to be unrelated to technical function or cooking techniques, and was more likely related to household size or the number of people food was being prepared for.

*Household Analysis, Ceramics, and Agricultural Sites:*

The evolution and cultural importance of the household has been explored in Oneota sites in Wisconsin. In particular, Oneota excavations in the La Crosse Terrace have yielded information about house structure differences, the social implications of the structure changes, and how it affected social interactions within the group. O’Gorman (2010) looks at the temporal shift in the use of the longhouse as the primary housing structure for Oneota in the La Crosse region. Possible ideology change, focusing “on membership in the corporate, labor-based longhouse community system” (2010:581) may have been a response to changing of social
factions and discord, in turn changing group identities. Goals of this change may have been
solidarity and peacekeeping though food sharing and community activity. Excavations revealed a
continual re-occupation of the same area, and even evidence of rebuilding of the same longhouse
structures.

A study of Middle Mississippian sites in the Cahokia region by Mehrer looked at all
debris types found in features, including faunal, lithic, and ceramics. Features were distinguished
by location, morphology and content, and significant discussion focused on differences between
interior and exterior features. It was observed that interior features were often smaller than
exterior ones, with exterior pits appearing to be placed relative to building walls rather than
corners (Mehrer 1995: 78-81). O’Gorman (2010) also observed storage pits located outside of
Oneota longhouse walls, noting the largest (over 450 liters in volume) were for storage purposes.
The results of Mehrer’s study looked at inter-household spacing and pit placement, as well as re-
use of areas for dwellings over time, representing areas determined ideal for dwelling placement

When it came to debris within pit types, Mehrer found small to medium pits contained
more exotic material, tools, and ceramics, with larger pits showing less archaeological debris.
The larger pits, such as abandoned house structure pits, were determined to have filled quickly
with soil, resulting in sparser accumulations of archaeological material (Mehrer1995:125). He
used ethnographic analogy to explain this observation: larger pits posed a possible hazard to
village life, thus explaining why they were often filled in more rapidly (Mehrer 1995:126). KCV
has many large pits and whether the same observations will prove true remains to be seen.
Household Archaeology at KCV:

Doing a household level analysis at the KCV site will present a few challenges that will affect the ability to discern certain social patterns. First, KCV does not have multiple full house structures excavated. Current understanding of the site suggests that both wigwam and longhouse style structures may have been used, but there is a limited sample of both. Nash (2009:223) suggests that the “way to avoid nonrepresentative and noncomparable domestic samples is to excavate entire houses.” When only a small number of houses have been excavated, Nash suggests that test excavations in known residential spaces can help examine broader social patterns, but cannot look deeper into the social dynamics of the community. The limited field excavations at KCV put this analysis in the latter category.

Excavation units in 2012, 2014, 2016, and most recently in 2017 have all been carefully planned to expose areas with the greatest surface artifact density, and to further explore possible rows of posts attributed to housing structures. The KCV spatial data support the idea that the excavated areas represent structures, but the overlapping features are not yet fully interpretable. Fortunately, several similar structures have been recovered at the nearby CBHC Hunt Club and Carcajou Point sites, which will provide comparisons and help fill in gaps in spatial organization (Gibbon 1968; Hall 1962; Jeske 2010; Moss 2010). However, as previously noted, the spatial organization of housing structures in relation to pit features will only aid in initial use interpretation, not the context in which features are excavated. Whatever data are analyzed from middens will provide insight into the domestic activities at the site as material was disposed of. Nearby housing structures may or may not have been occupied as material filled refuse pits, and association will not be possible without dating the housing structures themselves.

A similar study (Painter 2014), using the distribution of ceramics from previous survey
and excavation units on a grid map, looked at spatial patterns of the ceramic types to determine interaction between Mississippian and Oneota at the Crable site in Fulton County, Illinois. Painter was able to conclude that both Mississippian and Oneota households intermingled throughout the site, as each examined block contained both Oneota and Mississippian ceramics. Ritterbush (2006:157) described how ceramics associated with housing structures were used to determine interaction and possible cohabitation of Oneota and Central Plains tradition in the Late Prehistoric as Oneota groups moved into the area from the Midwest. Zych (2013) also looked at ceramic types within features at Aztalan, concluding that both Late Woodland and Middle Mississippians were cohabitating at the site during mound construction. These studies focused on how ceramics within features and housing structures could be used to determine social interaction.

Multi-material feature analysis by Moss (2010) at the nearby CBHC site explored the shift between two different dwelling structures. Seasonal occupation, a shift in post-marital residence, and structural function were all explored as possible explanations for the differing housing patterns. He found that only function of the dwellings were supported by his interpretation of the feature analysis, but he did not dismiss the possibility of seasonal occupation and housing shifts. In attributing functionality, Moss (2010:129) suggested the longhouse could have served as a “communal structure, where larger group activities such as mortuary rituals, harvest rituals, or others may have taken place, in addition to regular domestic activities, such as food processing and storage.”

Moss’s analysis can serve as an analogy to the data we might encounter at KCV. With a much longer history of excavations, a larger portion of the CBHC site has been explored. Despite some dissimilarities in their immediately surrounding environments, lifestyles were likely similar
for contemporaneous villages in the region, and the material at CBHC may provide clues for future results at KCV (Edwards and Jeske 2015; Jeske et al. 2016). With the explorations of the differing housing structures at CBHC and Carcajou Point, we might be able to hypothesize on housing patterns and social organization at KCV, despite having only a small portion of the site excavated.
CHAPTER 3

Methods and Expectations

This study relies on ceramics as a variable to examine the workings of Oneota households. Ceramic distribution across the site and between features is used to better understand site layout, household ceramic needs and production at the site, and possible implications for observed spatial patterns. These patterns, combined with site layout and collected carbon dates, can help us to determine how people lived at KCV over time.

Orton and Tyers define an assemblage as groups of pottery that in some sense belong together (1991:163). This can apply to a single context or feature, or a specific phase at a site. In the case of this study, the assemblage will refer to the entire collection of ceramics excavated from the KCV Oneota component during the 2012 and 2014 seasons of the UW – Milwaukee field school. All ceramics included in this study have established provenience, can be tied to a specific feature, and were collected through screening in the field with ¼ inch mesh. Because a larger proportion of the feature soil was screened in the 2014 season, there is more material from 2014. Surface finds have been excluded, as well as those found within the plow zone. Daub, or un-tempered and un-fired clay usually used in construction, was excluded as well.

Because of the deep plow scars, some features were partially obscured at the top of the subsoil level, and thus areas were assigned before the features could be properly distinguished. This was particularly useful in the 2014 season in regards to large overlapping features obscured by agricultural activity (Figure 3.1). The areas were easily tied to features as the soil was brought further down and the features became more clearly visible. Ceramics from these areas will be included in the analysis because they can be tied directly to specific features.
Vessel Typing:

The ceramic analysis portion of this study followed the type-variety system established by Schneider (2015), which built on and refined Hall’s (1962) seminal publication (Figure 3.2). Schneider kept well-known, established types in his schema, but expanded by providing new proposed types based on differing attributes. Attributes used in this schema include temper, surface treatment, and both lip and body decoration. Schneider’s types have become a standard comparison tool for different assemblages in the Koshkonong locality. The vessel types identified at KCV in this study include Busseyville Plain, Busseyville Trailed, Calumetville Crimped Plain, Carcajou Plain, Edgerton Punctate, Grand River Plain, and Koshkonong Bold.
Busseyville vessels are identified by a grooved paddle exterior surface treatment on the body of the vessel, created by a paddle with grooves carved into it or a paddle wrapped in leather cords (Schneider 2013; Stevenson et al. 2017). Busseyville grooved paddle technique appears to be a Koshkonong signature, being much more common at this locality than anywhere else in

Figure 3.2 Type-variety categorization from Schneider (2015). Types in red are common to the Koshkonong Locality, while those in gold are unique to the Koshkonong Locality. Types in green are more commonly found in other localities.

Busseyville vessels are identified by a grooved paddle exterior surface treatment on the body of the vessel, created by a paddle with grooves carved into it or a paddle wrapped in leather cords (Schneider 2013; Stevenson et al. 2017). Busseyville grooved paddle technique appears to be a Koshkonong signature, being much more common at this locality than anywhere else in
Wisconsin (Schneider 2013, 2015). Busseyville Plain is just the surface treatment, while the trailed variety has trailed lines on the body of the vessel. While most types in Schneider’s schema are defined by lip and body decoration, identification of a Busseyville vessel is unique in that it is simply identified by the surface treatment (Figure 3.3). Preliminary analysis of the 2012 ceramics noted Busseyville vessels tended to have squared or flattened rims (Carpiaux and Edwards 2014), however, this analysis has noted Busseyville vessels with unmodified and notched rims as well. Future studies should explore the efficacy of the Busseyville types since they do not adhere to the same lip form and body decoration standard of other vessels in the schema.
One of the non-local types noted on occasion in the area are the Calumetville Crimped types. This type is identified by a scalloped rim, created with fingers pressing in opposite directions along the rim (Figure 3.4). The result is a lip resembling a pie crust. This lip form is sometimes difficult to differentiate from Carcajou vessels, which are identified by a notched rim, created by either a finger or tool. The difference between the two types is that the notches on a Carcajou rim are created by pressing into the lip from one direction, while the crimped lip is formed by pressing the lip in two directions (Schneider and Richards 2010). Both Calumetville and Carcajou types come in a Plain and a Trailed variety. A Carcajou Plain vessel is simply a notched rim with a smooth, undecorated body, while Carcajou Trailed exhibits trailed lines in

Figure 3.4 Calumetville Crimped type from Schrage site (47FD0581) (Schneider and Richards 2010).
either a curvilinear or rectilinear fashion (Figure 3.5). Carcajou vessels are much more common in the Koshkonong locality than the Calumetville types (Schneider 2015).

Grand River vessels are identified by an unmodified or plain lip. The body is also smoothed, and can either be found in a Plain or Trailed variety (Figure 3.6). This type is

Figure 3.5 Carcajou Trailed type bowl from Schmeling site (Schneider 2015).

Figure 3.6 Grand River Plain and Trailed vessel types from Crescent Bay (Schneider 2015).
common in multiple localities, including the Grand River Locality from which it is named. Edgerton Punctate is similar to the Grand River variety, but includes both trailed lines and punctated decoration on the body of the vessel (Figure 3.7). The punctates are created by pressing the end of a tool into the surface of the vessel wall, resulting in a depression in the surface exterior.

![Figure 3.7 Edgerton Punctate from Schmeling site (Schneider 2015).](image)

Koshkonong Bold, so named for its prominence in the locality, is identified by bold trailed lines along the body of the vessel (Figure 3.8). A bold trail is identified as width equal to or greater than 10 mm. The Koshkonong Bold type, like the Carcajou type, has a notched rim. Other types in the area include Crescent Bay Punctate, Schmeling Plain or Trailed, and Carcajou Noded, but these varieties were not identified during the 2012 and 2014 field seasons at KCV.
Schneider’s type-variety vessel identification provides relatively simple categories for comparison both spatially and temporally. Due to high levels of fragmentation, however, typing vessels for KCV proved problematic. Since Schneider’s types rely on both lip form and body decoration, rims broken off at the neck are indeterminate in this schema. During vessel manufacture, the rim is added secondary to body production, making the neck a tenuous connection. It is common to recover rim sherds broken at this point, with over 80% of the KCV assemblage as unable to be typed (Figure 3.9). Thus, attributes are also analyzed for inter and intra-site comparison, as type-based studies may be too broad to compare trends (Raish 1977), especially with a sample as fragmentary as the one at KCV.

Figure 3.8 Koshkonong Bold vessel from KCV (S0021, V010).
Quantitative Measures:

Quantitative measures of this study are meant to provide easy inter and intra-site comparison. Certain clear measures by feature allows for spatial patterns to emerge, and comparison to other sites in the area more straightforward. In the literature, different methods for obtaining quantitative representation of ceramic quantity include full sherd count, weight, surface area, displacement volume, and minimum number of vessels. Often, weight is considered the fastest method, but sherd count the most accurate during statistical comparisons (Orton and Tyers 1991). Shott (2001) argues that count is a poor measure of quantity due to taphonomic reasons, and suggests weight and surface area as an alternative quantification. For this study, quantitative data collected from rim sherds includes count, weight, lip thickness, neck thickness, rim height, orifice diameter, and rim completion (see Appendix I: Ceramic Attribute Variable List). Quantitative measures for body sherds were count and weight.

This study includes both count and weight to ensure quantifiable and comparable analysis. Since quantity of sherds is not always easily established, especially with an assemblage that is highly fragmentary such as the one at KCV, weight will help establish just how much

Figure 3.9 Rim from KCV broken at neck (S0077, V047).
ceramic material was recovered from the site. Other measures, such as rim height, or lip and neck thickness, may be useful in temporal differences as well as the functionality of the vessel. Determining the number of vessels and total amount of ceramics recovered from specific features at the site will serve several purposes. As more of the site is excavated, we are getting a clearer picture of the ceramic needs and discard during typical village life at KCV. Larger groups of people living together will have greater ceramic needs to feed everyone, whereas smaller groups will utilize less.

Vessels were identified using rim sherds. To ensure vessels were not over-represented, all rim sherds within a feature were compared for re-fitting edges. If two rim sherds appeared to be the same vessel but did not re-fit, they were classified as two separate vessels unless matching rim profiles confirmed them to be the same vessel. Although literature suggests scattered discard of ceramic sherds in refuse pits due to secondary use, no re-fitted sherds have been detected from separate features in this assemblage (Boszhardt 2008; Schneider and Richards 2010). To be counted, a rim or body sherd must have been equal to or greater than 25 mm in diameter. If a sherd was smaller, it was classified as a fragment and weighed only. Both lip and neck thickness was recovered using calipers. The lip was measured at the end point of the rim at several locations and averaged, while neck thickness was measured with calipers perpendicular to the vessel wall at the point of vertical tangency (Figure 3.10). Rim height was measured at the neck from the point of vertical tangency to the end point at the lip. In certain instances, these measures could not be recorded due to damage or level of completeness.
Qualitative Measures:

Qualitative data collected will also serve essential purposes in this study. Qualitative data were recorded by observation and included appendages, lip and body decoration, temper, surface treatment, the presence of residue, and signs of use-alteration (see Appendix I for Ceramic Attribute Variable List). Based on the quantitative measure of orifice diameter, vessel size was estimated. These data were often obscured by the completeness of the sherd, damage due to excavation or deterioration, and even by the manufactured variation in the sherds.

These data were observed and quantified by a degree of intentionality. For instance, if a potential trailed line on a vessel appeared to be less intentional and more of a manufacturing defect, it was not recorded as decoration. One example from KCV (Vessel 034) appears to have trailed lines but they are non-continuous. These lines also bear a similar resemblance to the manufacturing lines from the interior of body Sherd 0065. Placement of the lines on Vessel 034 was also much higher on the neck as opposed to the body and shoulder where decoration is
typically found on Oneota vessels. Thus, the lines noted on Vessel 034 are likely due to scraping and re-shaping during manufacture (Figure 3.11), and was therefore recorded with no trailed decoration.

Appendages, such as handles, are useful in determining cooking styles. Loop and strap handles, as well as suspension hole perforations, can be used to position vessels over a fire or hearth for cooking purposes. Loop and strap handles are vertical with a hole through the center, while lug handles are horizontally aligned with the rim. Lug handles are more useful in carrying vessels, which may point to jars used for transport or storage.
Determining whether or not a vessel has decoration is essential to establishing types. Common motifs at KCV include the thunderbird punctates and nested chevrons, curvilinear interlocking scrolls, and vertical bold trails (Figure 3.12). These motifs are useful in determining important symbols and representations of ideology and world views. Examining motifs may provide insight into potential clan or totem affiliation (Benn 1989), while comparison between

Figure 3.12 Motifs showing thunderbird (top, S0036), curvilinear scroll (right, S0028), and vertical bold trailed (bottom, S0042) decoration from KCV.
sites and localities provide possible implications for trade and movement across the landscape (Schneider 2015)

Information about vessel function may be obtained from soot and residue. A large number of vessels have carbonized residue on the exterior of the vessels near the rim to the shoulder, suggesting signs of boil-over (Figure 3.13). Others show soot on a larger portion of the vessel body, which could indicate that the vessel was placed directly on a bed of hot coals for cooking purposes. Others still have little to no soot or residue, suggesting a cooking style of suspension over a fire (Kooiman 2016; Skibo 2013) or that the vessel was used for storage purposes. Spalling was also noted on several vessels, which can be an indicator of use as a cooking vessel but can also occur during firing (Figure 3.13). Since many use-wear analyses are based on more complete vessels, there is a noted lack of use-wear in this assemblage, despite the Oneota globular jar form as an effective cooking pot. For the vast majority of body sherds in this assemblage, the exact location on the body was unclear, making interpretation of use-wear patterns untenable.

Figure 3.13 Crusted exterior residue from boil over (right, V008) and spalling (left, V025).
Spatial and Temporal Analysis:

Although we only have five dates established from the site, this study can help indicate chronological patterns in ceramic styles at KCV. Further comparison to other sites in the area might help establish time periods in which certain types were utilized locally, or even show which styles were used long-term in the Koshkonong locality. Certain ceramic styles have been associated with early Oneota at sites in the Koshkonong locality, particularly those with lip modification and plain bodies, or those with curvilinear and rectilinear trailed motifs (Hall 1962; Richards and Jeske 2002). Overstreet (1997) contends that the Koshkonong Bold type dates between A.D. 1350-1650. It has also been suggested that Grand River undecorated rims date earlier than notched Carcajou rims in the locality (Jeske 2008, 2010). Continued verification of these trends at KCV will lend veracity to these trends in the locality.

Another comparison that may provide interesting insight would be vessel size within types or by feature break down. Vessels were categorized into small, medium, and large based on vessel orifice diameter, making comparison easier. An orifice of 10 cm or less is categorized as small, 11-20 cm as medium, and 21-30 cm as large. Anything larger than 31 cm in diameter was considered extra-large. Blitz (1993) notes that domestic contexts will have a wider variety of vessel sizes, while feasting and ritual contexts will show less size variation, with a focus on large-group food consumption and storage. Additionally, Kooiman (2016) demonstrated that vessel size differentiation in Woodland assemblages were unrelated to technical function or cooking techniques, thus size differences might be related to how many people are being fed, whether it be household size or feasting. Variation, or lack thereof, may inform on site population or household sizes, and patterns by feature might tie certain features to differing housing styles at the site.
The large amount of Busseyville body sherds (grooved paddle or smoothed grooved paddle) might also point to a significant pattern at KCV and the Koshkonong locality (Schneider 2015). Shell tempered pottery is overwhelmingly used in Oneota pottery, with the exception of relatively rare smaller, grit or un-tempered pinch pots. Literature suggests that shell or calcite as a tempering agent is an adaptation to a need for pots with more thermal shock resistance. Though shell-tempered pottery can be more difficult to fire due to spalling or other issues, it seems that shell-tempered pottery is more resistant to damage as a cooking pot from constant heating and cooling (Rye 1976; Feathers 2006). Additionally, corrugated or textured exterior surfaces also appear to contribute to thermal shock resistance (Schiffer et al. 1994:206-208), providing the Busseyville pot with a potential functional advantage over smoothed wares. Whether the Busseyville was intentionally manufactured for functionality or simply a stylistic choice, however, cannot be definitively ascertained.

Collection Procedure:

Template forms were created for mass analysis data collection. These data collection forms allowed for handwritten notes and sketches, as well as easy editing and reference. The ceramic assemblage from KCV is stored in boxes, with features and contexts separated by labeled bags. Sherds in which quantitative and qualitative data was to be collected (rims, decorated body sherds, and aberrant finds of note) were recorded on the Sherd Record Form (see Appendix II: Data Collection Record Forms). This document included the provenience, attributes, dimensions, measures, decoration, surface treatment, and of course a designation number for identification. Each recorded sherd was sketched and photographed, and a rim from each vessel profiled.
Because multiple rims could make up a single vessel, a Vessel Record Form was created for each identified vessel. This way the number of sherds, associations, and storage locations could be noted for each. Vessel form (or shape, Figure 3.14), size, and type, total orifice diameter, and decorative motifs were noted. Additionally, notched rim measures were noted on this record. Notch depth, width, and spacing (area on the lip between notches) was collected with calipers from every vessel with a notched decorated lip. Body sherd data was recorded using a Bag Record Form. This included provenience, bag contents, and associations to sherds in other bags (re-fitting sherds from separate bags). Contents recorded comprised the quantity and weight of recorded rims and decorated body sherds, count and weight of non-recorded body sherds, and weight only for rim and body fragments. Also noted was a breakdown by temper and the amount of plain smooth versus Busseyville body sherds. All attributes, both quantitative and qualitative, are noted in Appendix I: Ceramic Attribute Variable List.

Figure 3.14 Typical vessel forms and ceramic artifacts found at Oneota sites (Schneider 2015, Figure 4.2, pg. 141).
Ceramic Conservation and Repair:

Conservation and repairs to the sherds were done sparingly in order to preserve the ceramics in their original context and any potential residue for future analysis. If a recorded sherd was highly friable and additional handing and analysis may have damaged the sherd, stabilization and conservation procedures were used. Vessel repairs only occurred if the repair would enhance the understanding of the sherds themselves. Some sherds with re-fits were repaired to provide a more complete rim profile, while decorated sherds were occasionally repaired to aid in the interpretation a particular motif. One such example was Vessel 011, found with a unique “barbed wire” motif. Additional sherds found from flotation samples provided over 50% in rim completion, an understanding of how much of the body was decorated, and a suspension hole (Figure 3.15). All repairs were done after quantitative measures such as count and weight were complete to ensure completed repairs did not affect the data.

Figure 3.15 Completed repairs on Vessel 011, including the rim portion with a suspension hole (right) and an above image of the entire vessel demonstrating rim completion (left).
Repair and conservation procedure required additional documentation with the Conservation Report Form. This form includes vessel information such as provenience and vessel and sherd designations, and the condition and storage information prior to repair. The form then requires notation of documentation, cleaning methods, restoration procedure, and recommended storage after conservation. Photos were taken before, during, and after, and storage of sherds (reflecting recommended storage) noted after conservation and repair.

All conservation and repair was done with a solution of paraloid B-72 in acetone to ensure reversibility. Conservation or stabilization procedures usually employed low-concentration of B-72 (such as 2% or 5%) to consolidate friable sherds (Sease 1994). Repairs required a more extensive procedure. This began with consolidation of the entire surface of all sherds undergoing repair with a 2% solution of B-72. This was done to protect surfaces during repairs, since tape utilized while re-fit joins dried could cause damage to the surface upon removal. Following surface consolidation, re-fit edges were consolidated at 2%, 5%, and 10% B-72 in acetone. This was done to strengthen the re-fitting join edges. Repaired joins (especially using high-concentrations of B-72, such as 50%) are often stronger than the sherds themselves, thus joined edges need to be strengthened to ensure the repair holds. This can also cause further damage down the road if the join or consolidant is unstable (Newton and Logan 2007). After join edge consolidation, the repair was completed with 20% B-72 in acetone, and dried. Masking tape kept the joins secure while the B-72 dried. In some instances, when the repairs were tenuous or the sherds still fragile, a final coat of 2% B-72 was applied to the entire repaired surface after all joins were completed.
Documentation:

All documents used for data collection and conservation procedures are located in their blank forms in Appendix II: Data Collection and Conservation Forms. Forms were printed and filled out by hand to ensure quick and easy documentation during data collection and conservation. This ensured all collected data, sherd and vessel identification, provenience, storage location, and visual depictions originated in the same documentation, and were available to anyone using the collection. This was especially handy when specific sherds (such as suspected re-fits) needed to be located. These completed Sherd Record Forms, Vessel Record Forms, Bag Record Forms, and Conservation Reports are located in Appendices VII – X.

Hypotheses:

Based on the results of previous research, three hypotheses are laid out for this study. They focus on temporal patterns, vessel function, and household:

1. Temporal: It has been argued that certain ceramic types in the Koshkonong locality can be associated with early (or Emergent horizon) Oneota (Hall 1962; Overstreet 1997; Richards and Jeske 2002). Though pit features in the Koshkonong locality have a potential use life of several centuries (Stout and Skavlem 1908), radiocarbon dates from sites in the locality indicate an overlap in the two-sigma range when more than one sample is taken from the same feature. This indicates shorter-term use, or that zones in the vertical distribution are likely temporally distinct, and that artifacts recovered from the same contexts should date closely together. Therefore, types and motifs previously associated with early Oneota occupations should be found clustered within or in close proximity to early-dated features on a visual representation of ceramic distribution at
the site. A more equal distribution of types and attributes at the site may suggest they spanned multiple centuries, and thus cannot be definitively tied to an early occupation.

2. **Vessel Function**: Current understanding of the standard globular Oneota olla jar is that it is a multi-use pot designed to withstand cooking, as well as serve other functions including non-cooking activities. The shell temper, shape, and flared rim are ideal to cook over a fire or directly on hot coals (Berres 1998; Briggs 2016; Feathers 2006; Rye 1976; Schiffer et al. 1994). Use-wear alteration should help indicate function (Kooiman 2016; Skibo 2013). These use-wear alteration signs should be seen on all vessel types, thus supporting the assertion that Oneota ceramics are designed for multiple uses. If certain vessel types show no evidence of use-wear, this may suggest not all Oneota ceramics at KCV were designed to be multi-use, and that some styles may have other functions (i.e. ceremonial, storage, transport, etc.).

3. **Household Size and Interaction**: Previous research suggests larger pot sizes are tied to larger households or feasting (Blitz 1993; Betts 2006; Kooiman 2016). According to Blitz (1993), evidence of feasting can be observed by a narrow range of ceramic vessel sizes, mostly larger in size, where household and domestic contexts contain a wider range of vessel sizes. In addition, feasting activity requires sufficient storage for the surplus food needed for the feast (Kuijt 2009). The large pit features found at KCV offer potential evidence of surplus. However, food surplus cannot be assumed; storage may have simply served to ensure sufficient household provisions (Kuijt 2009). Features associated with larger households will have a wide range of pot sizes, including the larger sizes, whereas features associated with smaller households will exhibit a smaller range and will not contain larger pot sizes. If certain features can be connected to specific living styles, dated features might help to determine in what time periods those housing styles were used, even if that feature cannot be tied to a specific structure. A lack of spatial
distribution patterning in vessel sizes within features indicates an inability to interpret households from current excavation layout and data.
A total of 3,209 sherds and 41,494.3 grams (or 41.5 kilograms) were analyzed for this study, consisting of ceramic sherds larger than 25 mm in diameter excavated from the 2012 and 2014 seasons of the University of Wisconsin-Milwaukee Field School. A total of 242 rim sherds, representing 219 vessels were identified, with the remaining 2,967 identified as body sherds (Table 4.1). The overwhelming majority of sherds analyzed were shell-tempered (about 99%

total), while grit and un-tempered sherds accounted for under 1% (Table 4.2). Most of the grit and un-tempered sherds were from miniature vessels or pinch pots (Figure 4.1).

![Image](image.png)

**Figure 4.1** Decorated body sherd of an un-tempered pinch pot.

A total of 219 vessels were identified, most of which were olla jars with flared rims. On occasion, the rim flare was slight, some even with short, inward restricted necks were identified (see Appendix V for assemblage rim profiles). Other rarer vessel forms included four identified as pinch pots, three bowls, and one possible beaker. Three possible pipe portions were identified, but since they were not definitively determined so, they remained in the vessel category. One rim sherd could not be placed in any vessel form category and was designated as unknown.

As research has indicated, the vast majority of Oneota ceramics are globular, shell-tempered jars with flared rims and round bases. This assemblage was no different. Olla jars accounted for 94.1% of the assemblage at KCV, with the remaining 5.9% representing differing forms (i.e. miniature pinch pots, beakers, bowls, and clay pipes) (Table 4.3). A single cut sherd disk fragment was also identified.
Typing the vessels was problematic due to the fragmentation of the assemblage. Average rim completion percentage was only about 7.7%, with a mode of 5%. Of the 219 total vessels, only 34 (15.5%) were able to be typed. The most common typed vessels were Grand River Plain and Carcajou Plain with nine vessels each, followed by Busseyville Plain with seven vessels (Figure 4.2). Three rims were identified as Busseyville only, without enough body present to determine if they were decorated or not. Interestingly, all Busseyville varieties combined would outnumber either the Grand River or Carcajou vessels. This may be due to the unique type

attributes, as the Busseyville vessels have multiple lip forms, and other vessel type categories do not.

Since the majority of the assemblage was not able to be typed, attributes proved useful alternatives for analysis. Lip form indicated unmodified rims to be the most common, followed by notched lips (Table 4.4). This corresponds with the vessel types, as the first and second most numerous vessels are identified by unmodified and notched lips respectively.

Body sherds in this assemblage were mostly plain or undecorated, with 91.4% of body sherds falling into this category (Table 4.5). Plain body sherds number 2695 total with a weight of 31,567.6 grams, including both plain body sherds and plain body fragments. Only 44 total decorated sherds, and 208 sherds with a Busseyville grooved paddle surface treatment were identified. Only two cord-marked body sherds, reminiscent of Fisher-style ceramics from

</table>
northern Illinois, were identified (Figure 4.3).

The decorated ceramics consisted of five decoration types; rectilinear trails, punctates, bold trails, curvilinear trails, and painted (Figure 4.4). Only one painted sherd was identified (Feature 12-06), consisting of a single line of black pigment. Occasionally several types of

![Figure 4.3 Cord-marked body sherd from Feature 14-05.](image)

![Figure 4.4 Decoration type identified on body sherds.](chart)
decorative elements were combined such as rectilinear trails and punctates, or rectilinear and curvilinear. If enough of the decoration was visible on the body sherds, a motif was sometimes identifiable. These motifs include known designs including chevrons, scrolls, and thunderbird. Others were identified as common Oneota motifs (Hall 1960; Pozza 2016; Overstreet 1978, 1997; Schneider 2015) such as waves, vertical lines, and vertical lines under nested chevrons (Figure 4.5). Schneider (2015) identified several motifs common to certain localities in eastern Wisconsin. The motifs identified in this assemblage correspond with motifs typically found in the Koshkonong locality (Figure 4.6).

Most of the body sherds identified with decorative elements were too small to determine a motif, so the majority, or 42.6% of decorated body sherds, had unknown motifs. One vessel in

Figure 4.5 Waves (left, S0318) and vertical lines under nested chevrons (right, S0291).
particular, however, had the highest rim completion percentage at just over 50% recovered. This vessel was dubbed as having a “Barbed Wire” motif (Figure 4.7), consisting of trailed horizontal lines and short punctated marks directly above the horizontal trails. While less than 30% of the rim was originally found in the excavated area, the distinct decorative motif made for easy identification. This lead to additional sherds from this vessel being found in the flotation samples, thus increasing the rim percentage and body completion of the vessel. This included a
suspension hole in the rim. Since the refits were found in the flotation sample, these sherds were not included in the analysis. The vessel was, however, repaired for a better understanding of the shape and motif (see Appendix VII for the Conservation Reports).

Orifice diameter was used to determine vessel size. Of the 219 total vessels in the assemblage, an orifice diameter was able to be determined for about 85%, or 187 vessels. While mean was just slightly over 20.3, both the median and the mode were 20 cm with a standard deviation of 7.1 cm. Most orifice diameters were measured in whole numbers, but several
uneven sherds fit a range of vessels. The median value was recorded for rims with an orifice diameter range for data comparison purposes (Figure 4.8). Interestingly, the distribution of the vessels by orifice diameter is a fairly regular shape, with the majority of the vessel sizes falling within the standard deviation of the mean, median and mode, and slowly dropping off in frequency along the margins. Coefficients for skewedness and kurtosis are both below .1, showing remarkable symmetry and normal distribution (Table 4.6).

Based on orifice diameter, vessel size was estimated. Ranges for sizes were set at 0-10 cm (small), 11-20 cm (medium), 21-30 cm (large), and >30 cm (extra-large). The category cut-offs are fairly close to the standard deviations. Additionally, a relative spike in numbers occur at the larger end of the small and large category cut-offs of 10 cm and 30 cm (see Figure 4.8). The majority of the vessels were medium to large in size. They made up 79 (36.1%) and 80 (36.5%) of the entire assemblage. Small vessel number 21, making up 9.6% of the assemblage, while only 9 extra-large vessels were recovered, making up 4.1%. A total of 30 vessels, or 13.7%,
were of indeterminate size (Figure 4.9).

Schneider (2015) grouped his vessels into size ranges by natural breaks in the assemblage histogram. His size ranges were small (0-10 cm), medium (11-25 cm) and large (≥ 26 cm). He found that the Grand River Locality had a high frequency of both large and small vessels compared to the Koshkonong and Waupaca localities. While the CBHC site had a higher

frequency of smaller vessels, Schmeling had more in the larger size range. When converted to Schneider’s size ranges, the assemblage at KCV is more comparable to the assemblage at Schmeling than CBHC (Table 4.7) in terms of proportion (Figure 4.10). The variation between KCV and CBHC is statistically significant (Chi-square= 17.817, df=2, p=>.000), but the variation between KCV and Schmeling is not (Chi-square= 0.037, df=2, p=>.98).

Figure 4.10 Vessel size by site using Schneider's (2015) vessel size ranges.

Residue and other signs of use-wear were recorded when observed on both rim and body sherds. Recorded sherds with signs of use-wear included interior or exterior residue, flaring or soot, accretions, and signs of boil over. Only 39 sherds were recorded with signs of use-wear, all
on shell-tempered olla jar rims or body sherds. Carbonized residue, mostly on the exterior of the vessel, was most common.

In a few instances, a red film or white accretion was found on the interior (Figure 4.11). Evidence of both the white accretion and red film were found in different features, suggesting the activity that resulted in such residue occurred on more than one occasion at the site. The red interior film has been noted at the Gentleman Farm Langford site (Brown et al. 1967) and the Walker-Hooper Oneota site (Schneider 2015), and may be some sort of pigment. The white accretion on one of the sherds (S0012) excavated from feature 12-26 was tested with diluted hydrochloric acid for the presence of calcium carbonate. The test was positive (Carpiaux and Edwards 2017).

Activities were estimated by the type of use wear observed. Residue, flaring, soot, and spalling were designated as cooking activity. Instances of the white accretion and red pigment were designated as non-cooking activity. Cooking activity was the most commonly identified, at 87.2% of the noted use-wear. The residue found on sherds came from a number of different features and from different vessels, including Edgerton Punctate, Koshkonong Bold, Carcajou

![Figure 4.11 Red film (left, S0059) and white accretion (right, S0012) on the interior of body sherds.](image)
Plain, Grand River Plain, Busseyville Plain, and Calumetville Crimped Plain. It was also found on a number of un-typed vessels of differing lip forms. Evidence of cooking activity was also found on a variety of vessel sizes, from small to extra-large, most being noted on large vessels. Since vessels with differing attributes had use-wear related to cooking, this may suggest a variety of vessel types were used for cooking and food preparation.

**GIS Mapping:**

Variables were mapped in GIS to observe any possible spatial trends, showing both the 2012 and 2014 excavation units. Since several of the features were dated by materials excavated, these dates can be tentatively tied to ceramic styles excavated from the same features. By mapping ceramic variables, we can see them not only spatially, but talk about them in broad temporal terms.

Features 12-06, 14-05, and 14-29 contained the largest numbers of vessels with 49, 40, and 37 respectively (Figure 4.12). When looking purely at vessels by weight, Feature 12-06 is the highest, while 12-01, 14-05, and 14-29 follow (Figure 4.13). Each of these features yielded over five kilograms of ceramic material.

Other variables, such as average rim height, orifice diameter, rim completion, temper type, lip form, vessel type, and grooved paddle surface treatment were also mapped (see Appendix VI: GIS Mapping). For the most part, the largest features with the most ceramics recovered showed the greatest variety of types, lip forms, and vessels with non-shell temper (grit or un-tempered).

Grit sherds were recovered in 12-01, 14-05, 14-19, and 14-29 (Figure 4.14), while un-tempered pinch pots were seen in 12-06, 14-02, and 14-29 (see Appendix III: Data Tables for a
Figure 4.12 Spatial distribution of vessel counts by feature.
Figure 4.13 Spatial distribution of vessel weight by feature.
Figure 4.14 Spatial distribution of grit sherds by feature.
breakdown of temper by feature). Interestingly, the same features kept appearing when looking at attributes, including decorated or typed vessels, and even less common vessel forms like beakers, pinch pots, pipes, (Figure 4.15) or bowls (Figure 4.16).

Orifice diameter, which was used to determine approximate vessel size, was important to look at to determine how much food was being prepared at the site. This could aid in interpretations regarding how many people were being fed at the site, and potentially inform on the third hypothesis regarding household size. Average orifice diameter was mapped (see Appendix VI), as well as the resulting vessel sizes obtained by the orifice diameter. Medium and large vessels made up the majority of the assemblage, and also made up the majority of vessels in each feature.

The largest of the vessels were again found in some of the larger features, such as 12-01, 12-06, and 14-05 (Figure 4.17). These features, however, also contained very small sizes, showing a variety of vessel sizes. Feature 14-18 showed very little smaller sizes and a high average orifice and a single extra-large vessel. The exception was Feature 12-06, which contained six extra-large vessels, and 14-18 with no extra-large vessels. Orifice diameter, but no extra-large sized vessels, suggesting less variety of size. Larger features with a variety of ceramics often contained a majority of medium and large vessels, a few small vessels. Density of some variables was also determined, as counts and weights can change drastically depending on the density of the ceramics recovered in a feature. To determine density, volume was calculated by dimensions of the feature (width and depth). Then, the total amount of the feature that was visible, and how much was excavated vs. collected for flotation purposes (Table 4.8). This provided an estimate of approximate density of ceramics excavated from the feature.

</table>

Feature densities were an interesting comparison, as some features contained a large amount of ceramics, but were less densely packed with ceramics compared to some smaller features. Feature 14-29 was one of these, with the second highest count and weight of ceramics excavated, second highest count of vessels, yet low ceramic density and vessel density (Figure 14.18). Feature 14-05, also high in count and weight, has a relatively low density as well. Conversely features 12-04, 14-02 and 14-19 were low in count and weight, yet had higher densities.
Figure 4.18 Spatial distribution of vessel weight density by feature.
Decorative motifs were also mapped in GIS. Most of the features in which a large amount of ceramics were recovered also yielded decorated body sherds. Specific motifs, however, were not always evenly distributed among the features. Bold Trails, including rim and body sherds, were identified in features 12-01, 12-06, and 14-29 (Figure 4.19). Curvilinear body decoration was also found in these three features, as well as feature 14-19 (Figure 4.20). Trailed and punctated body decoration, often configured into a Thunderbird motif, was more widespread and was identified in 12-01, 12-06, 14-05, 14-18, and 14-29 (Figure 4.21).

CHAPTER 5

Discussion

While ceramic spatial trends were noted, very few temporal trends emerged from the data. To date KCV only has three dated features, and these observations may change as more of the site is excavated. However, the early, middle, and late occupation dates do give this study an initial look into potential temporal trends. Additionally, the ceramic data is a snapshot into domestic activities. Assemblage attributes, vessel form, use wear, and vessel size can all inform on the domestic life at KCV.

Feature 12-06 seems to reflect household refuse. This feature has a variety of ceramic vessel types, including Carcajou, Busseyville, and Grand River varieties. Ceramics are both plain and decorated, some with residue and flaring from cooking use. Other sherds showed no signs of use wear, suggesting these ceramics were potentially used for storage or decorative purposes. The feature also has two vessels with handles, indicating a utilitarian need. One vessel identified as a possible beaker or straight rim vessel came from this feature as well (S0131, V071; Figure

Figure 5.1 Possible beaker (S0131, V071) excavated from Feature 12-06.

84
5.1). This morphology might be similar to Powell or Ramey Incised vessels in the Cahokia hinterlands tied to specific functional and ceremonial uses (Crown et al. 2012; Miller 2015).

Feature 12-06 also has a large variety in vessel sizes, from small to large vessels. This includes small pinch pots as well as some of the largest vessels, with an orifice diameter upwards of 40 cm. It is unclear from the data alone if this pit reflects the refuse of a single household, but it could represent an extended family, multiple nuclear families, or a single nuclear family dump location for an extended period of time. Large households are often represented by a wide variety in vessel sizes (Blitz 1993), and larger vessels are more likely to be tied to feeding larger groups of people (Betts 2006; Kooiman 2016). The data and layout of the site suggests that Feature 12-06 is a larger household feature, evidenced by the close proximity to longhouse post molds.

As a comparison, Feature 12-06 is very similar to Features 12-01 and 14-05. They all have utilitarian ceramic assemblages, complete with use wear, as well as decorated ceramics and Busseyville grooved-paddle ceramics. They have the full range of sizes from small to extra-large vessels (albeit in differing amounts). The utilitarian assemblage, use-wear, and range in vessel sizes represent signs of household domestic refuse. Feature 14-05 shows additional similarities to Feature 12-06 in that they both contain bowls and fragments of pipes. One final similarity is the presence of red film on the interior of the vessels (Figure 5.2). This find is potential evidence of a red pigment and represent a non-cooking activity within the household space.

Feature 12-26 was a shallow basin of moderate ceramic density. Only one indeterminate rim was recovered; the rest of the ceramics were all body sherds. This feature contained a sherd (S0012) with interior white accretion, which tested positive for calcium carbonate. While calcium carbonate deposits are not a rare find on ceramic assemblages due to soil solutions (Freestone 2001), this particular accretion was abundant and isolated to a small portion of the
sherd (Figure 4.11). Few trends are gleaned from the ceramics alone, but when combined with analysis of macrobotanical materials recovered, evidence of possible domestic activities emerges.

Current studies on subsistence in the Koshkonong locality suggest the majority of caloric intake came from maize, and macrobotanical analysis supports this (Edwards 2017a; Edwards and Jeske 2017). Feature 12-26, however, is the only feature analyzed thus far in which acorns make up the majority of botanical remains recovered. This feature accounts for 80% of acorns recovered but only 8% of the flotation sampled (Carpiaux and Edwards 2017). One way historic groups processed acorns was to soak them in lye to remove tannic acids (Moerman 2010). A similar process was used to make hominy from maize (Briggs 2016). Carpiaux and Edwards (2017) suggest that the combination of these data might be possible evidence for acorn processing activity. Feature 14-05 also uncovered body sherds with white calcified residue,
indicating the activity that resulted in this accretion likely occurred on more than one occasion (Figure 5.2).

Feature 14-18, which revealed high average orifice diameter and low variety in vessel sizes, suggests that this may not be a typical household dump since household assemblages typically show variation. While one small vessel was recovered, the majority were still medium and large in size. This is more in line with typical evidence of feasting behavior (Blitz 1993). The feature is surrounded by several post-holes in a circular arrangement around it and another adjacent line of posts just south of the feature. This suggests a nearby structure, possibly related to the feature. More lines of evidence, such as faunal and botanical analysis, should be conducted to determine possible reasons for these results.

Feature 14-19 is a shallow basin that was an ashy grey color in comparison to the surrounding soil. This feature had a very high count and weight density of ceramics per cubic meter, and a large amount of Busseyville sherds were recovered. The vessels in feature 14-19 have some of the smallest average orifice diameter and shorter average rim height. These data suggest this may have been a ceremonial or single-purpose dump, and was not utilized for typical household refuse. Vessels size, however, indicates that only two of a total 13 vessels were categorized as small. Sample size may have affected the pattern noted in orifice diameter, as an extra-large vessel was also recovered from Feature 14-19. Future research consisting of dating techniques and archaeobotanical evidence may help elucidate the function of Feature 14-19.

Feature 14-29 is the largest feature by volume excavated to date, with over 14.91 cubic meters of soil. Interestingly though, it did not contain the most vessels, with Features 12-06 and 14-05 at higher counts. Additionally, sherd density by volume indicated Feature 14-29 to be less densely packed than other features, such as 12-01, 12-06, 12-26, and 14-19. Feature 14-29 does
contain a variety of vessels, including Busseyville Plain, Edgerton Punctate, Calumetville Crimped, and Grand River Plain. It also contains indeterminate un-typed vessels of notched, unmodified, flattened and squared lips. Feature 14-29 (along with 12-01) also contains the most small-sized vessels, with five total. Despite the massive size and relative low density, Feature 14-29 appears to have the makeup of typical household refuse, with a wide variety of vessel sizes and types. This density difference could be explained by vertical distribution and feature function before its use as a midden. While the upper levels of the feature were densely packed, the lower portion of the feature was filled mostly with sand and very few artifacts. It is possible this feature was left open for some time after utilization as a storage pit, allowing the bottom to fill partially before being re-used for household disposal (Figure 5.3).

Figure 5.3 Feature profile of 14-29 and 14-30 show overlapping and evidence of disturbance from rodents.

Features 14-02 and 14-05 have similar sherd weight density, but they differ in the total number of sherds. Feature 14-02 contains 7 vessels, while 14-05 has 41 vessels. Feature 14-02
was an estimated 1.46 cubic meters, while in comparison, Feature 14-05 was an estimated 3.22 cubic meters. Both features contained a single human bone incorporated into general site refuse.

The human remains found in Feature 14-05 showed evidence of cut marks and sooting from fire, suggesting disarticulation and processing (Jeske and Edwards 2014). The individual was estimated to be a young adult male. The human remains consisted of a set of articulated maxillae with no signs of intentional interment. The age was estimated to have been juvenile, and showed no signs of pathology or trauma. Feature 14-05 contains a variety of vessel types and sizes, and displays the typical household patter. Feature 14-02 contains less variety, but this is likely due to sampling. Evidence also suggests Feature 14-02 to be a household midden, but archaeobotanical and faunal analysis would help point further to use of the feature. There may be social implications for the disposal of human remains in middens without formal interment, but they are beyond the scope of this study.

Temporally speaking, many ceramic trends seem to span the entire occupation of KCV. This is made evident by looking at features 12-01 and 12-06. They rarely differ when looking at ceramic variables; both contain the same vessel and lip types, similar orifice diameters, rim height, and decorated body sherds. Both even contain similar motifs. One notable difference is that no Koshkonong Bold or Busseyville vessels are found in Feature 12-01, but bold decorated body sherds and Busseyville body sherds are recovered in Feature 12-01. While the sample size is relatively low, the data seem to suggest that these ceramic trends spanned the occupation of KCV. The excavations at KCV suggest that ceramic types and style are not sensitive to short-term temporal change, which may have implications for the rest of the locality.

Decorative motifs have often been used to identify ideology and cultural identity (Benn 1989, Schneider 2015, Pozza 2016). Thunderbird motifs, as well as claw or talon iconography,
are often associated with the upper world. Benn (1995) suggests chevrons and interlocking triangles are abstract depictions of raptor or thunderbird forms. In contrast, serpentine or curvilinear scrolls represent the underworld. Pottery found at KCV, and indeed sites throughout the locality, portray both these presumed representations of upper and lower world iconography. Interestingly, there does not seem to be any spatial or temporal separation between iconographic representations, suggesting both held the same importance and were utilized concurrently.

Acknowledgment of agency should be made in regards to decorative choice, especially since household ceramic production would rely on familial instruction. Schneider and Richards (2010) noted evidence of a specific ceramic type being proliferated by a single household at the Schrage site in Calumetville, Wisconsin. However, the motifs noted in the KCV assemblage are likely culturally significant, with widespread depictions of similar motifs throughout the locality spanning early and late occupation dates. Instead, agency and household variation may account for more subtle variation in attributes such as notch spacing or size, rim height, or clay source. Current data does not suggest temporal significance for these variations, but further excavations and future research may be able to explore these questions.

Implications for Hypotheses:

The first hypothesis in this study looks at temporal use of ceramic types. The hypothesis laid out in this study suggests that clusters of ceramic types or attributes should be noted spatially within features at the site, particularly in the dated features. Previous motifs, types, and attributes associated with early Oneota (e.g. Carcajou vessel types or curvilinear scroll motifs) should be seen in the same features, and more so in earlier dated features. Based on the data, the hypothesis is rejected, as most ceramics styles found at KCV have been found in early, middle, and late
contexts. The same attributes are noted across many of the same features in many of the GIS maps (see Appendix VI).

There are some exceptions, such as rare or non-local types like the Calumetville Crimped vessel, which was found in a feature dating toward the middle of the occupation at KCV. As only one crimped lip vessel was found, sample size is not sufficient to discuss temporality. Other common types in the Koshkonong locality, such as Busseyville, Carcajou, and Grand River vessels, were found to be present throughout the occupation at KCV. Koshkonong Bold, found in early, middle, and late dated features, also seems to have spanned the entire occupation at the site, demonstrating that the Horizon terminology based on temporal variation in ceramic types previously used to discuss Oneota cultural change is not supported. This may have implications for trade and movement of motifs, and the proliferation of the type from the Koshkonong locality to other localities.

The second hypothesis regarding vessel function and use-wear stated signs of use should be noted on all vessel types and differing attributes if we accept the current understanding of the Oneota globular olla jar as a multi-use vessel. As a multi-use vessel, the Oneota jar is designed to withstand cooking activity, as well as the potential to be utilized in storage, transport, and ceremonial functions. Based on the noted use-wear and lack thereof on the assemblage from KCV, this hypothesis is accepted. Recorded use-wear alteration was seen on a variety of vessel types, including Busseyville, Carcajou, Grand River, and Edgerton Punctate. All use-wear was noted on the globular jars with shell temper and flared rims. Vessels both decorated and undecorated, smoothed and grooved-paddle surface treatment were identified with use-wear. A lack of use-wear signs on these same types, as well as the red film residue, also suggests the
possibility of non-cooking activities. This lends credibility to the Oneota globular jar as a multi-use cooking pot, designed to work for a variety of purposes.

The final hypothesis for household size suggested vessel sizes could be used to estimate groups of people eating together. This could potentially indicate household sizes and how many people were living together in the same housing structures. The evidence of larger households (e.g. large range of vessel sizes, larger-sizes vessels, proximity to housing structures) was noted at the site, but direct ties to specific housing structures were not clear. The excavated pit features were interpreted from their use as refuse pits, but this was not the initial use of these pits. Originally built as storage caches or rice-threshing pits, their initial function likely influenced their original placement on the landscape. Though middens are often noted on the exterior of housing structures (Meher 1995; O’Gorman 2010), the housing structures noted in excavations may not have the same direct ties to the pits in their secondary use as the initial use.

For example Feature 12-06 dates to the later end of the occupation range. If this feature can be tied to a larger household, it might suggest larger housing structures being utilized toward the end of occupation at KCV. This conclusion conflicts with research at CBHC suggesting longhouses and larger housing structures were not utilized as living quarters, but communal spaces for gathering and ceremonial use (Edwards 2017a). It would be unlikely that Feature 12-06 would be a communal space dump, as communal activities such as feasting tend to show little variety in vessel size, most being larger in size (Blitz 1993). Feature 12-01 is also in close proximity, which dates toward the earliest occupation dates at the site. The larger housing structure might be just as likely to be tied to Feature 12-01, making direct association of these features to specific housing structures unlikely at this point.
Data initially suggests this hypothesis might have some merit. The extra-large vessels are mostly spread across the site in low densities with the exception of feature 12-06. The data from feature 12-06 is suggestive of a larger household, with a greater percentage (12.2%) of extra-large vessels recovered. Many of the larger features also contained a single extra-large vessel (Features 12-01, 14-05, 14-19, and 14-29). Feature 14-19 contained an extra-large vessel despite the overall low average orifice diameter of vessels from the pit. It appears food was cooked for large groups of people at certain times at KCV. While these features cannot be tied to a particular housing structure at the site, they are evidence for different activities and social structure at the site, as well as variety in living arrangements. With a variety of housing types identified in the Koshkonong locality, it follows that household makeup would vary. Due to the inability to directly tie pit features to specific housing structures, however, this can hypothesis cannot be answered.

What we can learn is that people are eating together. Whether they are living in nuclear family housing and coming together cooperatively to cook, or living together in large groups is uncertain, but it appears communal eating, and possibly feasting, was occurring at KCV during the Oneota occupation. Further excavations at KCV will help explore this as more of the site and housing structures are exposed.

**Comparison to Other Sites in the Locality:**

The ceramic assemblage is comparable to other sites in the locality. Proportionally, KCV matches up with the Schmeling and CBHC ceramic assemblages in types, but has slightly less diversity (Carpiaux and Edwards 2014). As more of KCV is excavated and the sample size reaches similar quantities to other sites, veracity of these trends should become clearer. Amounts
of indeterminate vessels due to fragmentation is comparable to Schneider’s data (2015), albeit slightly higher, and styles match up with those found at Carcajou Point, Schmeling, and CBHC. Amounts of notched rim Carcajou vessels, Busseyville grooved paddle sherds, and occasional rare finds such as Calumetville seem to be on par with observations at other local sites. Schneider (2014) has noted that the Koshkonong locality appears to have stronger ties to northern Illinois than other Oneota localities, as evidenced by Fisher-like vessels at Schmeling and KCV. The recovery of two Fisher-like cordmarked sherds at KCV continues to support this trend in the locality (Carpiaux and Edwards 2014). Any temporal suggestions regarding ceramic types and styles in the locality are, however, unsupported by the ceramics at KCV.

Conclusions:

The data at KCV suggest cultural continuity with other sites in the area, but have implications on social structure, populations, and shared ideology at the site. Vessels appear to be designed as multi-use tools, and the high degree of similarity is broken only by variety in decoration. Different functions could be carried out with a single vessel, making the Oneota cooking pot the Swiss Army knife in their food preparation arsenal. Decoration seems to span the entire occupation, with a variety of types and motifs appearing in both early and late dated features. It seems ideology remained relatively static in the area, as isolation of the Koshkonong locality limited contact with changing ideologies and lifeways in neighboring Oneota localities. Variation in size suggests both nuclear and extended households, or at the very least food sharing among households, at certain times during the occupation at KCV.

Future research at KCV and other sites in the area should expand on these observations. Further archaeobotanical and faunal analysis at KCV might confirm similarities to those shown
at CBHC, or show a difference that could explain housing disparities noted in this study.

Additional dating may expand our understanding of temporal changes in ceramics, and residue analysis may inform on vessel use in regards to subsistence and cooking techniques. With the newest field season at KCV already completed, future analysis should indicate whether the observations in this study continue to hold true, or if new patterns begin to emerge.

**Metric Measurements**

Count:  Any rim or body sherd greater than 25 mm in diameter.

Weight:  All rim sherds, body sherds, rim fragments, and body fragments weighed in grams.
Orifice Diameter: Rim orifice diameter measured at the lip on a radius measuring chart, recorded in centimeters.

Rim Completion Percentage: Recorded during orifice diameter using radius measuring chart.

Lip Thickness: Taken at multiple points along the lip at the end point and averaged, recorded in millimeters.

Rim Height: Measured in centimeters from the interior of the rim sherd from the point of vertical tangency to the end point at the lip.

Notch Width: Width of notch measured in millimeters using a calipers.

Notch Spacing: Space between notches measured in millimeters using a calipers.

Notch Depth: Depth of notch measured in millimeters using a depth gauge.

APPENDIX V

Rim Profiles

Profile Key:

- Indicates vessel number
- Indicates orifice diameter
- Indicates rim percentage

A solid line between the diameter and the rim percentage indicates a known orientation, while a dashed line indicates an unknown orientation. When an orifice diameter or rim completion percentage was indeterminate, it is marked as such (i.e. ind.).

A solid profile is the measured representation, while a dashed profile portion indicates a missing or unseen section of profile. Examples seen below include the profile without the handle present (V026) and exfoliated surfaces (V018).

CONSERVATION REPORT

Site Name: Koshkonong Creek Village (KCV)  Site Number: 47JE0379  Excavation Year: 
Recorded By: NEB & NAC  Date: 16 March 2017

VESSLE INFO:
Vessel No.: 007
Sherd No.: 0118, 0106, 0008, 0103

Condition: Good, though possible fragile on spots

PROVENIENCE:
Unit: 12-03, 04, 05 C8
Feature: FTF 12-010
Comments: 

PRE-CONSERVATION STORAGE:
Bags: 49, 85, 1
Boxes: 1

CONSERVATION PROCESS:

1. Documentation: Written + photographed

2. Cleaning Methods: Entire surface cleaned with 50% acetone + 50% water solution.

3. Restoration Procedures: Entire surface consolidated with 2% B-72 acetone solution. Sand consolidated with 5% B-72 and acetone. Frame completed with 20% B-72 acetone solution.

4. Recommended Storage: Place in its own bag, careful to protect joins – padding if possible.
PHOTOGRAPHY:

Pre-Conservation Images: 

During Images: 8553, 8554, 8571, 8620 - 8628

Post-Conservation Images: 8629 - 8632, 9500 - 9510

POST CONSERVATION STORAGE:

Bag: 232

Box: 

Comments: 

Notes: 

All jobs completed on 3/23/17.

Final weld all welds a new bag

3/18/17: the joined SO100 & 0118 were joined to SO008.

3/22/17: Final joint completed.

3/23/17: During cleaning, the final join failed. I realized the join edge was too small/weak. Final should be left separate.
Post join, drying:

Post join, pre cleaning:
Post break:

Final:

VEssel INFO:

Vessel No.: φφ9  
Sherd No.: 0013, 0014, 0015, 0018, 0019  0016

Condition: exfoliation along the neck, very dirty inside

PROVENIENCE:

Unit: D12-01, 02, 03, 04 Feature: FF12-01
Comments: Zone 7

PRE-CONSERVATION STORAGE:

Bags: 4

Boxes: 2

CONSERVATION PROCESS:

1. Documentation: written + photo

2. Cleaning Methods: 50% acetone, 50% water - Sherd #19 had dirt w/in crack - so broken + cleaned before reattaching

3. Restoration Procedures: 24% B72 in acetone applied to all surfaces
   5% 10% B72 in acetone applied to join edges - joins made w/ 70% B72
   Sherd #19 refit to exfoliated sherd - 8 1/2 cm from 14; then 16 to 13 then 15 to 4
   then 13 to 16 to 19

4. Recommended Storage: goes into added bag w/in original bag
PHOTOGRAPHY:
Pre-Conservation Images: 

During Images: 100 - 9352 to 9355, 2 re-consolidated pieces 9356 to 9357, exfoliated pieces consolidated 9369 - 9372, 9376 - 9378, 9381 - 9388, 9434 - 9437
Post-Conservation Images: 9443 - 9447, 9518 - 9526

POST CONSERVATION STORAGE:
Bag: 4 Box: 21
Comments: Placed in padded bag with original bag

Notes: 06/08/17 - The repaired neck did not properly adhere to the body, was removed. 
06/09/17 - S0015 broke off repaired rim. The edges were cleaned & re-consolidated. A broken fragment on body near neck join was also consolidated (with 2.5 + 10% B-72 in acetone). 2% B-72 was dripped into the exfoliating top edge of S0019 in an attempt to sturdy the rim join & prevent further exfoliation. 06/10/17 - Reconstructed rim sherds consolidated & joined to body. 
06/16/17 - Removed tape & cleaned excess B-72 w/ 100% acetone. Entire surface brushed w/ a final coat of 2% B-72 in acetone.
