ABSTRACT

LITHIC TECHNOLOGICAL ORGANIZATION AT THE AZTALAN SITE (47-JE-0001)

by

Robert Vander Heiden Jr.

The University of Wisconsin-Milwaukee, 2019
Under the Supervision of John D. Richards, Ph.D.

Chipped stone artifacts represent just one aspect of a complex framework of behavioral adaptations to social and environmental forces, each requiring significant investments of both time and energy. This project consists of a complete lithic analysis of all chipped stone materials recovered by University of Wisconsin-Milwaukee field schools during 1984, 2011, and 2013 from the Aztalan site (47JE01), located in Southeastern Wisconsin. This assemblage includes 1,202 pieces of lithic debitage and 200 chipped stone tools. Through employing individual flake analysis of all debitage, this thesis has produced a large database of information that can provide valuable insight into the technological choices made by the people who lived at Aztalan. While Aztalan is a multi-component site, radiocarbon dating has placed the major prehistoric occupation of the Aztalan site between A.D. 1000-1200 (Richards and Jeske 2002) therefore, this thesis focuses on the overlapping Late Woodland and Middle-Mississippian components. The major goal of this thesis is to characterize the chipped stone artifacts from Aztalan through an assemblage-based approach, with the intention of answering questions relating to the lithic economy at the site. The UWM lithic assemblage suggests that lithic technological organization at Aztalan changed over time. Statistical analysis of the data from this project shows that with increased Middle Mississippian interaction came increased access to non-local raw materials. Not only was there an increase in access to non-local raw materials, but raw materials were also heat treated significantly less over time. Additionally, the results of this project suggest that the
Late Woodland occupation at Aztalan may have already had access to a wider variety of raw materials than other Late Woodland groups in southeastern Wisconsin.
For my daughter, Melody

ACKNOWLEDGEMENTS

First, I could never have accomplished this without the constant love, encouragement and support of my family. I would like to thank my wife, Jessica and our daughter, Melody for their patience and understanding. I would also like to thank my father, Bob. Without his frequent inquiries into my progress and strong encouragement to “get it done”, this project probably still would not be complete. Of course, I must also thank my mother Sandy, whose unwavering pride in me has always motivated me to keep going.

Also, I would like to extend my great appreciation to my advisor Dr. John Richards for always being available to answer questions and provide guidance. I would also like to express my gratitude for the other two members of my thesis committee, Dr. Robert Jeske and Dr. Patricia Richards for helping keep me on track and eventually turning me into a better writer over the years, I know it wasn’t easy. Also, I am very appreciative of the help given to me by Dr. Pat Gray and Dr. Richard Edwards IV with the statistical analysis of the data for this thesis.

Finally, I would like to thank fellow University of Wisconsin-Milwaukee graduate students and UWM CRM employees; Kevin Akemann, Alexander Anthony, Eric Burant, Rachel Davies, Kaylin Garvens, Jennifer Picard, Andrew Saleh, Rachel Schultz, Marcus Schulenburg and Megan Thornton. I will always be grateful for their friendship and advice over the course of my graduate career at UWM. Special thanks go to Rob Ahlrichs, Jeremy Doyle and Dr. Katherine Sterner, for putting up with my nearly constant questions regarding raw material types and tool form classifications.
Chapter 1:
Introduction

Thesis Statement

This thesis is a comprehensive analysis of excavated chipped stone materials from three excavation seasons at the Aztalan site (47JE0001) located in southeast Wisconsin. The project examined 1,197 pieces of lithic debitage and 200 chipped stone tools and represents the first such analysis of a lithic assemblage from the site. All materials analyzed in this thesis were recovered by University of Wisconsin-Milwaukee field schools in 1984, 2011, and 2013 and are curated at the UWM Archaeological Research Laboratory. The data set used in this study was recovered from multiple distinct areas of the site that were created by discrete depositional events during different temporal periods and includes two pure Late Woodland assemblages. These areas include a Late Woodland living surface in the Plaza and a Late Woodland stratum in a stratified midden. Mixed Late Woodland and Middle Mississippian assemblages include stratified midden deposits, a mixed context pit feature, and mound fill from the Northeast platform mound. The data set offers a unique opportunity to look for differences in the organization of lithic technology spatially as well as temporally. The organization of lithic technology is “the way in which a culture or society designs its tools and structures tool production, use, and maintenance, so that the tools can respond effectively to the demands placed upon them by the society in its daily interactions with the environment” (Koldehoff 1987:153). As previously mentioned the goal of this project is largely to characterize the lithics from Aztalan with the intention of answering questions relating to efficiency at the site. Another goal of this thesis is to discuss chipped stone tool technological organization spatially, by comparing data from five different areas of the site; the plaza, the northeast mound, an area within the residential area of Aztalan
referred to here as the northeast woodlot, and two areas of midden stretching along the bank of the Crawfish river. Finally, another major goal of this thesis is to test the expectation that with greater social complexity there will be a greater need to organize chipped stone technology efficiently (Jeske 2002). It is expected that because of the additional costs of time and energy associated with the introduction of Middle Mississippian culture, efficient adjustments lithic economy in would have been required. To test this idea, differences in the organization of lithic technology over time at Aztalan are examined through comparing isolated Late Woodland context materials to mixed Late Woodland/Middle Mississippian context materials.

*Site Background*

The Aztalan site is located on the west side of the Crawfish river in Jefferson county Wisconsin, about five miles north of the confluence of the Rock River. The site is situated in portions of the SE ¼ of the SE ¼ of Section 17, and the NE ¼ of the NE ¼ of Section 20, Township 7 N, Range 14 E (Fig. 1.1). The archaeological site consists of a palisaded mound-and-village complex oriented around a central plaza area (Richards 2007:5). Radiocarbon dating has placed the major prehistoric occupation of the site between A.D. 1000-1200 (Richards and Jeske 2002). Twelve-foot high palisade walls made from single posts plastered with mud and grass fortified approximately 9 hectares. Every 20-25 meters square bastions projected outward from these palisade walls leaving no portion of the enclosure unprotected. An interior palisade wall enclosed approximately 2.5 hectares of the eastern portion of the site adjacent to the river. This area is believed to have been the major domestic habitation area based on archaeological evidence that suggests that most of the domestic structures, pit features, hearths, and midden concentrations are located within this enclosure (Barrett 1933; Birmingham and Goldstein 2006;
Platform mounds were constructed in the southwest, northwest and northeast corners of the enclosure and the southeast mound is a naturally occurring gravel knoll in the southeast corner (Fig. 1.1). Recent geomorphic testing conducted into the southeast mound during excavations by Michigan State University in 2013 suggest that this gravel knoll had been modified and two radiocarbon dates have calibrated median probabilities that span A.D. 1093-1186 (Richards and Zych 2018; Kolb 2015; Harrison and Goldstein 2015). The northeast mound was described by Increase Lapham in 1850 as a rectangular mound extending 15 meters north to south and at least 30 meters west to east (Lapham 1855; Richards and Zych 2018). Recent core sampling by Michael Kolb suggest that mound fill could extend much farther west to east and the northeast mound may have been up to 70 meters long (Kolb 2015; Richards and Zych 2018). The southwest platform mound is a “stepped truncated pyramid built up from the eastern face of a gently sloping hillside” that appears to have been constructed in three stages (Richards and Zych 2018:242). The footprint of the southwest mound is square shaped and covers approximately 2,240 square meters (Richards and Zych 2018). Also built in three stages, the northwest platform mound has a rectangular footprint covering roughly 800 square meters (Richards and Zych 2018). A burned mortuary structure was discovered on the second stage of construction that contained the remains of 11 adults that were then covered by a third stage of mound construction (Richards and Zych 2018; Rowe 1958). A concentration of large pit features that has been referred to as a “sculptuary” is located just south of the northwest mound and is believed to be related to its use (Richards and Zych 2018; Goldstein 2010). Roughly 170 meters west of the northwest corner of the outer palisade wall is a line of ten conical mounds often referred to as “marker mounds” that once stretched north for approximately one quarter mile (Richards and Zych 2018). Dr. John Richards carbon dated organic remains from three of these mounds,
curated at the Milwaukee Public Museum and results suggest that the construction of these mounds likely post-date the mid-twelfth century and were contemporaneous with the Mississippian occupation at the site (Richards 2017). Figure 1.2 shows a map illustrating the layout of the site and figure 1.3 is a mural by MPM artist George Peters circa 1937, of what the village at Aztalan may have looked like. The Aztalan site became a Wisconsin State Park in 1952. The site was designated a National Historic Landmark in 1964 and was listed in the National Register of Historic Places in 1966 (Wallace 2000).

Project Background

This project is a detailed analysis of chipped stone artifacts recovered during three field school excavations conducted at Aztalan by the University of Wisconsin- Milwaukee (UWM). In 1984, a field school directed by Lynne Goldstein excavated a total of 17 test units at the site. These test units were placed in two distinct areas of the site that were created by very different depositional events. These two areas included a portion of the plaza area and an area of exposed midden in a ravine along the riverbank (Richards 1992). During the 2011 and 2013 field seasons 18 more test units were excavated in three more areas of the site; other portions of the riverbank, the northeast woodlot and the northeast mound precinct. In this thesis I describe the chipped stone tool and debitage assemblages from these three excavations and discuss what it suggests about the way the people of Aztalan organized technology to adapt to both their physical and social environments.
Aztalan has been professionally investigated archaeologically for almost 100 years. This has led to a variety of studies and interpretations of the material culture of the site. Ceramic assemblages recovered from the site have been studied by numerous researchers addressing questions about typological frameworks, temporal assignments and cultural affiliations (Baerreis
and Freeman 1958; Barrett 1933; Bleed 1970; Hurley 1977; Kotwasinski 2014; Mollerud 2005; Richards 1992; Stoltman 2001; Zych 2013). Aztalan harbors a mixed Late Woodland with Middle Mississippian occupation with the primary Late Woodland component composed of collared ware producing groups (Richards 1992). Aztalan is one of the few archaeological sites in Wisconsin where both Madison ware types and collared ware types occur with Middle Mississippian ceramic forms (Overstreet 2000). Petrographic analyses of ceramic sherds in addition to isotopic analysis of human teeth recovered from Aztalan demonstrate the movement of people from the American Bottom to the site (Price et. al 2007; Richards, et. al 2010; Slater et. al 2014). Analysis of the pottery in the collection at the Milwaukee Public Museum (MPM) suggests that the Aztalan ceramic assemblage is approximately an even split between Late Woodland grit-tempered pots and shell-tempered Middle Mississippian vessels (Richards 1992: 208). Faunal materials have been analyzed suggesting that animal consumption patterns not only varied between different areas of the site, but also changed over time with the addition of the Middle Mississippian population (Warwick 2002; Leigl 2014). Likewise, floral analysis has shown that the Middle Mississippian presence had a definite effect on agricultural practices at the site over time as well (Picard 2013). These shifts in subsistence practices likely reflect efforts to maximize efficiency in response to increased populations and the creation of a more complex society.

Regrettably, lithic technology and its organization have not been studied as extensively at the site. The reason for this bias is simple, stone tool assemblages from the late prehistoric era are often overshadowed by the large amounts of information provided by other data. Additionally, Middle Mississippian people would not have been using stone tools much differently than Late Woodland groups, and in fact, employed similar lithic strategies utilizing
“mundane flakes detached from bipolar and amorphous cores” to carry out a wide variety of tasks (Cobb 2000).

Although at a glance, late prehistoric lithic assemblages appear simple, there is good reason for it. Between A.D. 300 and 1300, populations in the Midwest increased dramatically. “Broad trends associated with this rise include increasingly intensive utilization of local resources, increased sedentism, and higher input into food-gathering technology, culminating in an agricultural economy based on field clearing and tending of maize” (Jeske 2003:233). These population surges and the intensification of maize agriculture occurred around the same time as the early Mississippian period referred to as the Lohmann phase (A.D.1050-1100) (Benson et. al. 2009). During the Lohmann phase the American Bottom was the setting of a dramatic economic and political reorganization (Benson et. al. 2009; Pauketat 1993; Pauketat and Emerson 1997; Emerson 1997; Alt 2002; 2012). This restructuring included the movement of large numbers of people from dispersed village settlements to large urban centers like Cahokia located near the modern city of St. Louis. At Cahokia, “A major political upheaval occurred at the beginning of the Lohmann phase, involving a rapid ascendency of a new form of centralized authority and political community” (Benson et. al. 2009:471; Slater et. al 2014; Alt 2002; 2012). Climate fluctuations may have fueled these changes. Recent studies analyzing tree-ring based indicators of climate change, suggest that this transformation likely took place during one of the wettest periods of the last thousand years, followed by about 145 years of persistent droughts (Benson et. al. 2009). It is believed that Cahokia reached maximum population levels during the Lohmann phase and it is likely that the ruling classes would have found it increasingly difficult to maintain power. Agricultural support from outside sources supplemented Cahokia’s growing population creating a complex system of rural farming communities that were linked to urban centers which
were ultimately associated with Cahokia. While Aztalan is clearly linked to the American Bottom during Cahokia’s expansion, given the great distance between Cahokia and Aztalan, it is unknown exactly the extent of contact that was maintained between the occupants of these two sites.

Fig. 1.2: Aztalan site layout (Birmingham and Goldstein 2006: XII Fig. C)
Throughout the Midwest, the transition from Late Woodland lifeways to those of Middle and Upper Mississippian groups is not well understood by archaeologists (Jeske 1992b). Some Late Woodland groups appear to have readily adopted Middle Mississippian subsistence strategies and ceramic traditions, while other groups chose not to fully integrate these changes or to not accept them at all. Additionally, many sites outside of the American Bottom that include Mississippian components appear to retain many local Late Woodland characteristics with hybrid ceramic styles often present (Emerson et al. 2007; Picard 2013). Aztalan, located well north of the American Bottom, offers a unique perspective on this transition. At Aztalan, there does not appear to have been a great resistance to this change but rather the creation of a new shared communal identity (Zych 2013). Both Late Woodland and Middle Mississippian groups practiced farming and grew maize as well as other domesticated cultigens (Picard 2013). However, data suggests that Late Woodland groups in southern Wisconsin generally relied on maize agriculture less than the Middle Mississippian groups of the American Bottom (Picard 2013).
Indeed, the greatest transformation for the Late Woodland residents of Aztalan may have been their relatively sudden inclusion into the complex social networks and intense religious practices of the Middle Mississippian world. Technology, conceptualized as “the body of knowledge a society draws upon to cope with its environment” (Koldehoff 1987:152-153) may have been the least affected aspect of late Woodland lifeways. Nonetheless, aspects of lithic technological behaviors may reflect changes in social structure and subsistence strategies resulting from this transition to a hybrid society. When groups of people live more sedentary lifestyles, restrictions on access to resources tend to increase. We can then assume that as a result these groups would incur an increased level of risk because as groups of individuals restrict themselves geographically, the local resources they depend on may become exhausted or put under extreme stress (Jeske 2003; 1992a, 1992b). Maintaining trade networks as well as the cultivation of storable crops can help alleviate some of these stresses. Though raising crops anywhere is always a gamble, weather as well as insect activity can be extremely unpredictable especially in southeastern Wisconsin and can rapidly destroy entire crops. With good luck and hospitable weather conditions, agriculture can produce large surpluses. However, because not all neighboring groups may experience the same amount of success, raiding is also a constant risk. At Aztalan, inhabitants were obviously concerned with reducing these types of risks by building large palisade walls with defensive bastions to protect their village. When engaging in activities such as raw material procurement and tool manufacturing these risks must be considered so that strategies can be adjusted accordingly to ensure the highest potential return on investments of time and energy. Robin Torrence has discussed multiple possible strategies for maximizing returns on investments in lithic technology (Torrence 1983; 1986). Sophistication of formal tool designs can ultimately reduce the cost of human labor through making improvements in the
equipment used to successfully complete tasks. Simplification also helps to control cost because by reducing the total quantity of labor through reducing the stages of production, a great deal of time can be saved (Torrence 1986). Standardization involves the exploitation of accumulated knowledge passed down over generations and involves identifying the most simple and efficient production techniques, so that a rhythm of work can be reached in which knappers become particularly skilled at tasks performed repeatedly (Torrence 1986).

Another way risk can be reduced is by establishing and maintaining hospitable relationships between neighboring groups. However, these complex social relationships also require significant amounts of time and energy to maintain. Therefore, “since time and energy are limited resources, we must expect that groups investing in these activities may be tempted to conserve in other areas such as lithic procurement and tool manufacture” (Jeske 2003:233). Stone tools and debitage from the site therefore offer insight into how the occupants of Aztalan not only navigated their physical and social environments but also how they negotiated the risks that were involved with them. As the population at Aztalan increased with the addition of Middle Mississippian occupants, lithic resources would have become even more stressed. At Aztalan, there are no good local sources of chert, limiting procurement of raw materials to what could be found in the glacial till and what could be obtained through trade. This means that the inhabitants of Aztalan should have been forced to economize in the production of chipped stone tools. Heat treatment of raw materials can improve the workability of certain types of chert (Rick 1978; Dunnell et. al. 1994, Jeske et al. 2010). A higher frequency of heat treated debitage is an example of a deliberate effort to improve the quality of raw materials and extend their value. Another example of economizing lithic resources is bipolar reduction, which is a stone tool making technique in which raw materials are placed on an anvil and struck with a hammerstone to
remove flakes (Jeske and Lurie 1993; Jeske 1992a; Shott 1989). Bipolar reduction is believed to have been utilized prehistorically when raw materials were scarce to reduce small cobbles of locally available stone found in glacial deposits or riverbeds (Jeske 1992a).

Chapter 2:
Background Research

Previous Lithic Analysis at Aztalan

Archaeologists have given surprisingly little attention to the organization of chipped stone technology at Aztalan. The first attempt to describe the stone tool industry at the site was by Samuel Barrett in 1933. In 1909 Barrett became the first professionally trained anthropologist to work in Wisconsin when he joined the staff of the Milwaukee Public Museum. In 1919, 1920 and again in 1932, Barrett led MPM crews on excavations at Aztalan. These were one of the first professional and systematic archaeological excavations at any site in the state (Birmingham and Goldstein 2006). Barrett’s ambitious project not only targeted the ruins of the palisade walls which surrounded the site but also sampled other areas of the site including a variety of houses and associated domestic features located within the riverbank palisade enclosure of the site (Clauter and Richards 2009; Richards 1992). In addition, Barrett tested each of the three platform mounds as well as each of the ten conical mounds northwest of the enclosed portions of the site and other nearby effigy mounds (Clauter and Richards 2009; Richards 1992). He published his findings in 1933 providing the first description of the lithic technology of Aztalan (Barrett 1933). Barrett’s analysis combined the materials he recovered from his excavations, as well as
collections of surface finds donated to the MPM by several local relic collectors (Barrett 1933; Sampson 2008). Barrett broadly classified 358 projectile points as either unnotched, notched, serrated, or lance points. According to Barrett “the predominant type of point here at Aztalan appears to be the [unnotched] triangular one, with the equilateral or approximately equilateral form” (Barrett 1933:267). Of the 358 projectile points in Barrett’s sample, 295 (83%) are of this unnotched type, and these unnotched points either display a square or a concave base. However, most of this type (90%) have square bases. Barrett reports a significantly lower number of notched points however; these points display a greater range of variation than the unnotched points. According to Barrett “the notched base point is of special interest because it is such a rare and specialized form… [that] forms one of the strong links between Aztalan and certain sites farther south in the Mississippi valley, particularly Cahokia” (Barrett 1933:267). Six points in Barrett’s’ assemblage (three notched, three unnotched), show evidence of serration on their edges (Barrett 1933:266). Fourteen larger points, are categorized loosely as lance points although Barrett admits that it is questionable whether “lance” is an accurate descriptive term (Barrett 1933:268). According to Barrett all the points were made from three materials: quartzite, chert, or translucent quartz. Barrett also notes that “Quartzite is the most characteristic and predominant material, somewhat more than half of the points being made of this material” (Barrett 1933:266). Additionally, a range of different types of quartzite is reported as displaying a large variety of colors including white, grey, black, brown, and red (Barrett 1933). While quartzite is the overall dominant material present, within the category of notched base points chert seems to be the only material used (Barrett 1933). Interestingly, eighteen points were found that were made of a clear translucent variety of quartz. Barrett also describes fragments of two large bifaces, assumed to originally have been 200-250 mm in length, and a large biface made of
a pinkish chert that he presumed was probably a type of knife-like implement (Barrett 1933). Another group of chipped stone tools he reported are described as re-chipped, rounded implements called “bunts” (Barrett 1933:269). According to Barrett, while he only recovered five of these “bunts” during his excavations, after including the collections of relic hunters, “we can say that there are approximately two thousand such pieces” included in the sample (Barrett 1933:269). Additionally, thirty-seven tools referred to as drills, all of which were made from chert except one made of quartzite, are described morphologically, as ranging “from very long, slender, unnotched drills, through the various broad-based, and notched types to the extremely short and stubby forms” (Barrett 1933:271). Three more artifacts are also discussed which at first were classified as drills, but upon closer examination Barrett classified as chisels. These tiny chisels are about 52 mm long and 9 to 14 mm wide and, according to Barrett, are “one of the most interesting chipped stone implements found here [at Aztalan]” (Barrett 1933:271). Barrett also describes five flint spades or hoes, made from a specific raw material found in southern Illinois called Mill Creek chert. Mill creek hoes were highly valuable and prized items which have been found hidden along house walls and in abandoned storage pits in the American Bottom (Milner et. al. 2010) Additionally, two quartzite fragments were recovered which resembled this spade form (Barrett 1933). These quartzite spade fragments are interpreted by Barrett as most likely an attempt “to translate the southern flint spade into materials more commonly found in the Aztalan region” and furthermore “such evidences of borrowing of cultural traits, particularly in pottery, are rather clearly shown here at Aztalan” (Barrett 1933:272). Finally, Barrett commented on a single artifact of reddish chert which was bifacially worked into a square shape and was most likely a heat-treated, recycled biface fragment. Figure 2.1 shows Barrett during his excavations at Aztalan.
From 1949 through 1952, excavations by the Wisconsin Archaeological Survey (WAS) concentrated on locating and excavating three prehistoric house features as well as the recovery of information needed to restore the southwest and northwest platform mounds and the outer palisade walls (Clauter and Richards 2009). In 1958, Robert Maher and David Baerreis published an article titled *The Aztalan Lithic Complex*. The Maher and Baerreis study provided a brief summary of the lithic assemblage excavated by the Wisconsin Archaeological Survey and compared their data to that of Barrett. Maher and Baerreis also analyzed an assemblage of chipped stone tools consisting of 237 Madison triangular points (43 from the WAS excavations and 194 from the Barrett excavations). While Barrett found quartzite to be the predominate raw
material, Maher and Baerreis credit chert as the most frequently used material. (Maher and Baerreis 1958:8-9).

Maher and Baerreis applied statistical analysis to the measurements of their Madison Triangular points. The length and width measurement data were submitted to a simple analysis of variance (Maher and Baerreis 1958:12). The goal of the analysis was “to test whether or not any aspects of the culturally directed construct in the minds of the workers responsible for the artifact type might be quantifiably expressed and statistically analyzed” (Maher and Baerreis 1958:11). They compared the data from Aztalan with five Oneota sites; Midway Village, White Camp Site II, Walker-Hooper Village, Carcajou Point, and Lasley’s Point. Interestingly, their results showed that while there are no visible differences between the Madison points from these sites, “Oneota artisans held in common a similar idea of point dimensions…with the Aztalan point maker showing a significant preference for a wider and longer point than did any of the other groups investigated” (Maher and Baerreis 1958:13). In their article, *A Statistical Analysis of Some Mississippian Projectile Points* published in 1960, Elden Johnson and Craig Henrikson of the University of Minnesota, Minneapolis attempted to test the reliability of Maher and Baerreis’ conclusions. Johnson and Henrikson performed the same test on a similar group of six Oneota and Middle Mississippian sites. The results of their study contradicted the results of Maher and Baerreis in that Johnson and Henrikson did not observe significant differences between the length and width of any of the point groups they tested in their study (Johnson and Henrikson 1960).

Fifty years after the Maher and Baerreis study, Kurt Sampson conducted a comprehensive diachronic and comparative analysis of 289 of the projectile points excavated by S.A. Barrett. According to Sampson, “analysis of these 289 projectile points demonstrates
several trends such as the high use of exotic silicified sandstone at Aztalan during Late Woodland and Middle Mississippian periods, a general trend in the decrease of projectile point size and refinement from Archaic times through Mississippian times, and the continual use and increased heat-treatment of moderate quality, local chert materials through time” (Sampson 2008:123). Overall, Sampson identified 17 different diagnostic point types consisting of 18 different lithic material types (Sampson 2008). Diagnostic point types from the collection appear to date from the Early Archaic period through the Middle Mississippian occupation, displaying an 8000-year span of site utilization (Sampson 2008). However, Sampson found that Late Woodland and Middle Mississippian types made up 85% of the 289 excavated projectile points in the assemblage (Sampson 2008).

Many excavations have been conducted at Aztalan since the Barrett excavations and the WAS excavations. During 1964, 1967 and 1968 Dr. Joan Freeman conducted excavations for the State Historical Society of Wisconsin. These excavations focused on recovering information concerning house types and documenting the northeast mound (Freeman 1986; Richards 1992). Also, excavations conducted in 1962 by William Hurley focused on documenting portions of the east, west, and southern palisade walls (Hurley 1977; Richards 1992). Unfortunately, most of the materials recovered during these excavations have remained unanalyzed and unreported (Richards 1992; Zych 2015).

Dr. Lynne Goldstein has also conducted extensive work at the Aztalan site, overseeing excavations for UWM during 1984, 1988 and 1996, and excavations for Michigan State University during 2001, 2002 (Pfaffenroth 2018). In 2013 Goldstein also codirected a joint field school for Michigan State University with Dr. Sissel Schroeder from the University of Wisconsin-Madison and Dr. Donald Gaff of the University of Northern Iowa (Goldstein 2015).
The focus of these excavations was on conducting test excavations into the “gravel knoll” in the southeast corner of the palisaded area and on excavations outside of the main palisade in the southwest corner of the site (Goldstein 2015; Pfaffenroth 2018). Dr. John Richards also conducted excavations at the site for UWM in 2011 and 2013. These excavations will be discussed in greater detail throughout this thesis. Most recently, in 2015 and 2016, Dr. Sissel Schroeder from the University of Wisconsin-Madison conducted field school excavations at the boundary of the residential area and plaza and attempted to locate domestic structures within the residential area (Pfaffenroth et. al 2017; Pfaffenroth 2018). While there has been a large amount of fieldwork conducted at the site, regrettably much of this work remains unreported and published reports often do not include lithic analyses.

As previously mentioned this thesis focuses on the analysis of materials from three UWM field schools conducted in 1984, 2011, and 2013. In 1984, Dr. Lynne Goldstein led a UWM field school at Aztalan with two objectives in mind; recover information concerning site formation processes and assess the integrity of remaining archaeological deposits (Richards 1985, 1992). To accomplish these objectives, two sets of test excavations were conducted; one centered on an area of riverbank midden which had been reported by Barrett while the other targeted an area referred to as the Plaza, an enclosed, L-shaped area believed to have been used for public ceremonies and feasts (Birmingham and Goldstein 2006). The careful, systematic midden excavations have provided the only stratigraphically discreet layers containing mixed Late Woodland and Middle Mississippian materials on top of deposits solely associated with Late Woodland culture, offering the opportunity to look for changes in technologies over time. In addition, the Plaza excavations encountered the partial remains of a structure and associated pits
that appears to be a pure Late Woodland occupation based on the presence of Late Woodland pottery and the absence of Mississippian ceramic wares (Richards 1985, 1992).

During the 2011 field season Dr. John Richards led an Advanced UWM Archaeological Field School at Aztalan. The goals of this project were to locate and interpret in situ stratigraphic sequences which might help interpret the period of Late Woodland and Middle Mississippian occupation and also shed light on the timing and cause of the site’s abandonment (Richards and Picard 2013). In one of the excavations into a section of midden stretching along the riverbank, a test unit revealed an intact lens of ash and charcoal, designated as Feature 8. The northwestern half of this feature was excavated before the end of the 2011 field season. This portion of the feature produced a very rich assemblage of material culture including lithics, sheet copper fragments, grit and shell tempered pottery as well as an unusually wide variety of floral and faunal specimens. Kernels of maize recovered from Feature 8 were submitted for AMS radio carbon dating and produced a date of 910±15 B.P. (ISGS A2636) (Picard 2013). This date, combined with the data from the material culture, has placed Feature 8 in the early Mississippian phase of the site’s occupation with a median probability date of calibrated A.D. 1084. Dr. Richards returned to Aztalan during the 2013 field season while instructing another UWM field school. The major goals of the 2013 project were to return to the riverbank midden area, remove the 2011 backfill and recover the remaining southeastern portion of Feature 8, and to locate and define the extent of the northeast platform mound.
Chapter 3:
Methods of Analysis

Theoretical Models

Optimal foraging models have been successfully used by evolutionary ecologists in attempts to “explicate strategies of predation or adaptation [in nonhuman species] which are optimal with respect to specific criteria (generally those strategies which maximize the fitness or survival potential of the individual or population)” (Keene 1981:172). Bruce Winterhalder and Eric Smith have worked extensively to show that optimal foraging can be just as useful when applied to groups of contemporary hunter-gatherers and as a result, others have been able to employ optimal foraging theory to the study of prehistoric human behavioral patterns (Winterhalder and Smith 1981; Bamforth and Bleed 1997; Jeske 2003). According to Robert Jeske, while “optimal foraging models were initially articulated in regard to food gathering… they can just as well apply to other resources, such as stone tools” (2003:225). Moreover, Douglas Bamforth and Peter Bleed add that through the employment of optimal foraging theory “archaeologists focused on flaked stone tools have derived substantial insights into the relations between technology and such factors as mobility patterns, complex economic organization, raw material availability, and cultural or ethnic preferences” (1997:110). Arthur Keene (1981) proposed that optimal foraging theory is based on a set of simplistic assumptions that are based on our current understanding of natural selection. First, we assume that the patterns we observe in the archeological record are real and reflect decisions made by humans to fulfill certain needs. Next, we assume that these activities are directed toward providing both the food and non-food resources necessary for survival and that “there is selection across time in favor of behaviors which satisfy these requirements, and that this satisfaction is facilitated through cultural
mechanisms that govern food preferences and choices” (Keene 1981:173). The third assumption is based on the ideas of utility and cost. Utility refers to the overall value of a resource and cost refers to what one must give up because of the decision to use one strategy over another (Keene 1981). It seems obvious that it would always be desirable to reduce costs as much as possible while still maximizing the overall utility of a resource. Although utility can mean different things to different groups of people or even individuals, here we assume that when these groups are faced with making a choice between two resources that provide the same amount of utility, the resource that costs the least to obtain will be viewed as more desirable than the costlier option. Likewise, we also assume that “faced with an array of resources of varying costs and varying utilities…the combination of resources which can satisfy basic needs at the lowest possible cost” will be chosen (Keene 1981:173). As a result, at some level, prehistoric groups of foragers needed to evaluate their costs in terms of the different types of currencies required to reach the optimal balance of both cost and utility. Currencies may include various proportions of time and energy that are required for the initial search to find a resource as well as the time and energy required to successfully pursue, obtain and process that resource (Keene 1981). Other types of currency might include the essential nutrients provided by that resource, or the risk of either failure and/or injury (Keene 1981; Smith 1981). Energetic efficiency, a combination of the amount of energy used and the effectiveness of that energy, is an especially useful type of currency because “it allows costs of foraging to be measured in the same currency as benefits—a problem with many alternative formulations” (Smith 1981:51). In addition, another assumption of optimal foraging is that resources are limited and can be unpredictable, which directly effects the cost and utility of those resources. These costs can be lowered not only through technological means, but cultural means as well such as reciprocity, redistribution, food storage and
information sharing (Keene 1981). Environmental restraints, either physical or social, can limit the choices groups have in procuring not only food resources, but raw materials as well, which then, in turn affects the variation we may or may not observe in archaeological assemblages. In its application to archaeology, Keene has argued that hypotheses based on optimal foraging theory should not be viewed “as a means of verifying optimality in prehistoric subsistence behavior, but [instead] viewed as a means of augmenting an incomplete data base, and of generating predictions about behaviors which might not have been obvious had we relied on the archaeological record alone” (Keene 1981:189). In other words, the point is not simply to test these hypotheses because in many ways these models are oversimplified. However, optimal foraging models can help to identify discrepancies between these models and the data that force archaeologists to ask important questions about the causes and implications of these gaps (Keene 1981).

By maximizing efficiency both in stone tool production and carefully planned raw material procurement strategies, risk of failure is greatly reduced. Bousman offers four criteria by which efficiency can be measured; quicker production time, increased use-life, increased effectiveness, and increased production of volume (Bousman 1993). Expedient tools are made for the fulfillment of immediate needs and are therefore categorized morphologically by little alteration or secondary shaping (Bousman 1993:69). Expediency is a desirable strategy because “expedient technologies dramatically reduce the costs associated with transporting raw materials to manufacturing and use locations, and their use reduces time spent on tool manufacture and repair” (Bousman 1993:70). Another approach to efficiency in stone tool manufacture and use is the construction of maintainable tools. Maintainable tools are tools that have been designed with the idea that costs of raw material acquisition are significantly reduced by extending the use-life.
of a tool through maintenance such as re-sharpening (Bousman 1993). According to Bousman, “maintainable tools can be multipurpose and made to work even after broken… [and] can also be used for tasks other than those for which they were originally designed, i.e., recycled” (Bousman 1993:70). Taking this idea further, some groups find it necessary to construct what Bleed refers to as reliable tools, which are functionally specialized and are characterized as being very well-made with extra attention paid to the critical parts of the tool that directly affect the tools effectiveness and may even include their own repair kits containing easily replaceable spare parts (Bleed 1986; Bousman 1993). It can be expected that reliable tools will be employed when the risk of failure needs to be greatly reduced due to the importance of the task and perceived severity of consequences resulting from failure (Bousman 1993). Through careful consideration of stone tool assemblages, archaeologists can begin to identify these strategies. To accomplish this goal, not only can we look at proportions of tool types, but we can also look at the debris that is the result of certain decisions made during tool production (Jeske 2003).

One way to approach this issue is by calculating flake-to-tool ratios. Flake-to-tool ratios represent the total number of debitage divided by the total number of tools. A low flake-to-tool ratio at a site might suggest that tools were rarely produced or repaired at the site and the existing tools were more likely to simply be replaced. On the other hand, a “high proportion of flakes to tools...suggests a higher level of repair, reworking and resharpening of tools at the site” (Jeske 2003:235). Furthermore, the overall intensity of tool use at a site also informs us of the importance of efficiency to the prehistoric inhabitants of archaeological sites. Proportions of complete tools recovered compared to broken tools can reflect the level of efficiency in stone tool use as well (Jeske 2003). If most tools are broken, we assume that they have been fully exhausted of all utility. Additionally, tool recycling and scavenging are also recognizable
behaviors that suggest a strong desire to reduce costs associated with raw material procurement (Jeske 2003).

If these behaviors reflect an attempt to reduce costs associated with the procurement of raw materials, then obviously locating and choosing the best sources for these materials is one of the most important decisions involved. Raw material sources may be chosen based on many characteristics such as the quality of the raw material, the utility of the material for making specific tools, or by geographic, environmental or social restraints that would have likely made sources difficult to capitalize on. The proportions of local raw materials compared to non-local types may then indicate different mobility patterns or participation in social institutions such as long-distance trade networks. In technologies “tools are not just tools, procurement strategies are not just procurement strategies [instead] each is differentiated and organizationally adjusted to the other, so that there may be one kind of procurement strategy suitable for the supply of one class of tools and another considered to be suitable for different classes of tools” (Binford and O’Connell 1984:428). However, in some cases obtaining raw material is simply incorporated into other activities such as seasonal subsistence rounds, and in other cases groups make special trips to obtain raw material specifically. Costs and benefits related to the physical properties of different raw materials also have a direct influence on technological behavior. For instance, good quality raw materials can be considered expensive because the cost of time and energy for procurement and use is high (Jeske 1989). Bamforth (1986) suggested that raw material availability is an important influence on variability in lithic assemblages because the quality and abundance of local raw materials will decide how efficient a technology must be (Bamforth 1986; Jeske 1987).
Instead of a more traditional morpho-functional analysis, this thesis takes an assemblage-based approach to present data describing lithic technological behaviors in more economic terms. An assemblage-based analysis is advantageous because it works to avoid possible misinterpretations due to misleading assumptions about tool use that are possible when relying on morpho-functional based typologies alone (Flenniken and Raymond 1986; Jeske 1987; Sterner 2012; Wilson 2016; Winkler 2011). Through examining the ways in which prehistoric cultures organized technologies such as chipped stone tool production through an economic lens, we can gain insight into how variations in behaviors across an archaeological assemblage fit into the broader context of a cultural system (Andrefsky 1994; Bamforth 1986; Jeske 1987; 2003; Shott 1986, Sterner 2018; Wilson 2016). Organization of lithic technology is a process involving not only the manufacture and use of tools but also raw material selection and procurement. Subsistence strategies, settlement patterns, social complexity and level of access to quality raw materials are all factors that limit the maintenance of an efficient lithic economy. Furthermore, technical requirements may impose limits on the design of tools such as size and weight which must be satisfied to maximize the effectiveness of the tool.

Lewis Binford (1979) first described lithic organization on a continuum ranging from formal curated tools to expediently made tools. Curated or formal tools such as bifaces and formally prepared cores are made with the anticipation for future use carrying out multiple tasks and are usually transported and ultimately recycled for other uses (Andrefsky 1994). On the other hand, expedient or informal tools, are made to quickly complete an immediate task at hand, fulfilling the needs of the moment and then are discarded soon after use (Bamforth 1986; Binford 1979; Torrence 1983). Using ethnographic data, Binford argued that curation is dependent on mobility and that highly mobile foraging populations efficiently organized lithic technology by
producing curated tools because they occupy large areas and must have tools ready at any moment. Because sedentary populations do not need to produce portable tools, Binford argued that it is more efficient for these groups to produce expedient tools that do not require advanced knowledge to create and do not require much energy to maintain. (Binford 1979). Robin Torrence (1983) then introduced the idea of time-stress, which shapes the scheduling of different activities due to time constraints. Producing expedient tools for immediate use becomes more efficient for sedentary populations then because of the difference in the time it takes to produce the tool. Using expediently made tools means less time and energy spent making or maintaining portable tools so that tasks may be completed faster, spending the least amount of energy while receiving the highest possible return. Robert Jeske has further argued that the use of efficient technologies such as formal and standardized tools, are responses to the level of energetic efficiency required by lithic technological systems, balanced against additional demands for energy in other aspects of society (Jeske 1987). According to Jeske, “the greater the complexity of the social network- alliances, social rankings, intergroup violence- the larger the share of a group’s energy budget that must be devoted to these activities” (Jeske 2003:226). For example, if resource availability is the only limiting factor, we may expect more evidence of economizing behavior related with materials associated with utilitarian rather than ceremonial contexts, but if social factors also necessitate an increased expenditure of energy to obtain acceptable quality raw material, then attempts to economize will be made to lower the cost of using that material or simply lower the standards of acceptability (Jeske 1987). Therefore, the ability to effectively distribute time for tool manufacturing is dependent on social complexity, mobility, and the availability and quality of raw material sources.
Jeske tested the expectation that with greater social complexity there will be an increase in energetically efficient behavior by analyzing chipped stone artifacts from the LaSalle County Home site in northern Illinois. He compared lithic assemblages from a Woodland occupation excavated at the site in 1987 with a later Upper Mississippian occupation excavated in 1993 (Jeske 2002; 2003). Jeske looked at flake-to-tool ratios, the frequencies of local versus non-local raw materials, quality of raw materials, intensity of tool use, tool breakage, recycling and scavenging (Jeske 2003). He found that the Mississippian inhabitants of the site used economizing approaches such as the “use of a lower variety and/or poorer quality raw material, the production of more efficient tools, and the use of tools longer and more completely-compared to the practices of the Woodland occupants” (Jeske 2003:235).

Data Collection Methods

There are two potential ways to approach lithic debitage analysis. One approach is individual flake analysis, in which each piece in the assemblage is observed independently. The other approach is mass debitage analysis, where large quantities of debitage are analyzed simultaneously to obtain summary parameters (Odell 2003:120) Individual analysis was conducted on all the chipped stone tools as well as all the debitage from the assemblage used for this thesis. While individual flake analysis is more time consuming than mass analysis, it can produce a large amount of valuable information about the technological choices people made when producing and maintaining stone tools. Data for the lithic assemblage was collected following an adapted version of the Lithic Documentation and Schema (Jeske 2014) developed by Lurie and Jeske (1990). Using this schema is advantageous because it produces basic data sets that “enable researchers to address questions about settlement patterns, procurement systems,
social networks, and a multitude of other issues that affect raw material acquisition, tool production, tool use and tool discard [and] the compatibility of data sets also allows the research to make comparisons within or among regions and to identify stability or change through time” (Jeske 2014:2).

Chipped stone artifacts from the UWM Aztalan assemblage were previously sorted by various UWM student volunteers. Data was collected beginning with the 2013 materials and proceeded through the materials collected during the 2011 season and then the 1984 excavation materials. All data was collected by the author at the UWM Archaeological Research Lab during the spring of 2018. Data was entered into a database using Helix database management software as it was being collected. Data was then exported into an Excel spreadsheet for analysis. Tools and debitage within each provenience were first separated so that they could be analyzed individually. In addition to formal chipped stone tools, all debitage that showed evidence of modification such as re-touch or use-wear were also categorized as tools. A 10x magnification jeweler’s loop was used to identify use-wear on flake tools. After recording all known provenience data, tools and debris were assigned identification numbers within their assigned lot numbers.

*Individual Flake Analysis*

Important provenience information was first entered into the database for each artifact. This information included site name and number, project number, lot number, the excavation unit number and the feature number when necessary, the level number and depth, and the site area. Then each piece was given a debris number within the lot. In addition to provenience
information, fifteen variables were also observed and recorded for each piece of debitage. Based on observations of basic form each piece of debitage was categorized into one of three types; flake (including bipolar), flake-like or non-flake. The presence or absence of certain flake characteristics such as a striking platform, a bulb of percussion, concentric rings of force, or typical flake terminations such as feather, step or hinge terminations determined how each piece was typed (Jeske 2014:17). If a piece of debitage displayed two or more of these characteristics it was considered a flake. Broken pieces which only displayed one of the flake characteristics were categorized as flake-like. While pieces of shatter that did not display any of the flake characteristics but were still considered to be byproducts of tool manufacturing were categorized as non-flakes.

Next, raw material type was determined for each piece when possible. Raw material types were determined by the author using a comparative collection housed at the University of Wisconsin Milwaukee Archaeological Research Lab (UWM-ARL) and by using the Wisconsin Lithic Resource Guide (Winkler, et al. 2009). Heat treatment of raw materials was identified based on notable changes in raw material color and luster, prominence of conchoidal ripples or the presence of heat fracturing such as pot lid fractures or crazing and was recorded as either present, burned, possible, or absent. Quality of raw materials was characterized as either good, fair or poor. Raw material quality refers to the flaking quality of the raw material and is often determined by the size and number of inclusions, grain size, and fracture plains (Jeske 2014). Percent of cortex or patina present on the dorsal surface was estimated through visual inspection and was recorded as either 0%, less than 50%, 50% to 99%, or 100%. If the striking platform was present, it was described as either bifacial/complex, prepared, unprepared (cortical), or collapsed. Platform angles were measured using a contact goniometer and were recorded as
either 0°-45°, 46°-90°, 91°-135°, 136°-180°, greater than 180°, cannot determine or not present.

When present, bulbs of percussion were described as either pronounced, diffuse or multiple. Likewise, ripples or concentric rings of force, were identified and described as either pronounced, diffuse or not present. The presence or absence of an *éraillure* scar which is a small flake scar on the ventral side of a piece of debitage near the bulb of percussion, was recorded as present, not present, or indeterminate. Types of terminations were recorded as either feather, hinge, step, outrepassé, shatter or no termination, crushed, or indeterminate. Next, flake scars on the dorsal surfaces of all debitage were counted unless the dorsal surface could not be identified. All debitage was then graded by size into one of four size categories; less than 8mm, 8mm to 12.5mm, 12.5mm to 25mm or greater than 25mm. Finally, each piece was weighed using a digital scale so that individual weights could be recorded.

*Chipped Stone Tool Analysis*

In addition to provenience information, twenty-six qualitative variables that reflect manufacture, function, and style were recorded for all the chipped stone tools in the assemblage. Raw material types, raw material quality, the presence or absence of thermal alteration and the amount of cortex present were recorded for the tools in the same way as previously described with the debitage. Tools were categorized into one of seven types of basic tool form; edge or functional unit only, unifacial, bifacial, multifacial, blade, and unknown. Expedient tools that showed no evidence of shaping but instead showed simple evidence of retouching or use-wear were categorized as edge or functional unit only tools. Unifacial tools were those tools shaped on only one side of the body and bifacial tools were those that were shaped on both sides. Each must possess at least one flake scar that does not originate at the edge of the shaped face (Jeske
Multifacial tools often have a blocky appearance and exhibit seemingly intentional flake scaring on more than two faces of the body. Nonfacial tools are usually formed by battering and use rather than intentional modification and are often rounded and do not have any well-defined faces or edges. Prismatic blades or bladelets may or may not show use wear and are defined as flakes with parallel edges and at least one ridge running the length of the dorsal surface and is usually much longer than it is wide (Jeske 2014). Tools that were categorized as unknown were fragments that had been modified in some way but were too incomplete to assign to any other category.

Edge modification refers to the location of modification on the edge of a tool (Jeske 2014) and was recorded as unifacial when modified on only one side of an edge, bifacial when modified on both sides of an edge, unifacial and bifacial when there were at least one of each type of edge segment present, or not applicable if there were no edges present. Method of modification describes how the edge or body of the tool has been modified and were classified as either flaked, battered, flaked and battered, use-wear only, retouched and used or not applicable. Edges were considered to have been flaked or retouched when flakes appeared to have been intentionally removed from the body or edge resulting in at least three contiguous flake scars that extend more than 1 mm onto the body of the tool and 0.5 mm or more along the edge of a tool (Jeske 2014). Poorly defined edges or surfaces with indistinct flake scars produced by pounding were identified as battered edges. Use-wear refers to obvious signs of use including grinding, polishing, rounding or flaking that does not extend more than 1 mm onto the face of the tool.

Tools with a bifacial basic form were given a refinement score. Refinement scores were either crude, medium or refined and were based on comparisons with sample pieces within the UWM comparative collection. Some of the basic criteria for the scoring refinement were the size
of flake scars along edges, regularity of tool outline and thickness of transverse cross-section (Jeske 2014:10). Tools that were too incomplete were scored as can’t determine, and tools that did not have a bifacial basic form were scored not applicable.

Completeness was scored as either whole, broken, cannot determine or not applicable. If any of the edges were interrupted by a break, then the tool was scored broken while questionable tools were scored can’t determine. The elements present variable then identified whether all elements were present or which parts of the tool were present if it was broken. Elements present were scored as either; distal end, mid-section, proximal end, end section, all elements present or can’t determine. If the distal end was present, then distal end morphology variable was scored as either blunt, pointed, if it was not present then the score was not applicable or can’t determine. If an edge appeared to have been dulled or broken previously and then resharpened, then the reworking or reuse variable was scored as either present or possible, if not then it was scored as absent. Position of retouching or use was recorded as either end, side, end and side, can’t determine or not applicable.

The number of reworked or used edge segments for each tool was counted and totaled. Then the edge angle and edge configuration were recorded for each edge segment. Edge angles were recorded using a contact goniometer and were scored as either 0°-45°, 46°-75°, greater than 75° or not applicable. Edge configuration for each edge segment was scored as either smooth, serrated, denticulate, notched or not applicable. Hafting elements were scored as present, possible, absent or not applicable. Projections were areas defined by intentional retouch or by wear on an unretouched area of the tool that extended out from the body (Jeske 2014:13). Projections were scored as either present, absent or not applicable and modification on projections was likewise scored as present, absent, or not applicable.
Finally, length, width and thickness for all chipped stone tools was measured using digital calipers and a digital scale was used to weigh every artifact. Length was measured along the longest axis while the longest axis perpendicular to length was measured as the width and the greatest axis perpendicular to both length and width was measured as the thickness (Jeske 2014:14).
Lithic Debitage

The debitage assemblage from the 1984, 2011 and 2013 UWM field schools at the Aztalan site, recovered from 4 different depositional contexts, consists of a total of 1,197 pieces of chipped stone debitage weighing a total of 1334.54 grams (Table 4.1). Of this total, 43.4% displayed some amount of cortex and 47.1% displayed some evidence of heat treatment. As previously mentioned, debitage was then graded by size into one of four size categories; less than 8mm (1), 8mm to 12.5mm (2), 12.5mm to 25mm (3), or greater than 25mm (4). The assemblage is dominated by size 3 (67%), followed by size 2 (16%) and size 4 (13%) with size 1 debitage (4%) the least represented in the assemblage. However, these results may be affected by data collection methods used in the field such as screen size or the collection of flot samples (Table 4.1). Although generally, the debitage is not very large with a mean weight of only 1.12 grams per piece.

Again, based on observations of basic form each piece of debitage was categorized into one of three types; flake, bipolar flake, flake-like or non-flake. The presence or absence of certain flake characteristics such as a striking platform, a bulb of percussion, concentric rings of force, or typical flake terminations such as feather, step or hinge terminations determined how the basic form each piece were typed (Jeske 2014:17). The assemblage is dominated by flakes (54%) and flake-like pieces (25%) followed by non-flakes or shatter (20%) (Fig 4.2). Only 11 pieces (1%) were classified as products of bipolar reduction. However, Robert Jeske and Rochelle Lurie have argued that it is impossible to differentiate the two techniques by dividing the debitage assemblage into free-hand and bipolar categories because analysts will likely combine the two techniques (Lurie and Jeske 1993:145; Wilson 2016). Only one of these bipolar flakes was made from non-local, good quality Burlington chert while the rest were local or unknown raw material types. Most of the bipolar flakes were made from poor quality materials (55%) and had some amount of cortex (73%) or showed signs of heat treatment (64%). It should also be mentioned that six pieces of debitage in the collection were noted as possible bipolar flakes but did not display enough conclusive evidence. Non-flakes or shatter, are probably also products of bipolar reduction and show a high frequency of heat treatment (53%). Also, the shatter was mostly produced from poor quality raw material (61%) that possessed some amount of cortex (52%).

Debitage Raw Materials

Raw material types were determined for each piece when possible using a comparative collection housed at the University of Wisconsin Milwaukee Archaeological Research Lab (UWM-ARL) and by using the Wisconsin Lithic Resource Guide (Winkler, et al. 2009). A variety of raw material types were observed within the assemblage (Fig. 4.3).

</table>

While there is quite a variety of raw material types present in the assemblage, 59% of the debitage consists of locally available raw materials (Table 4.4). Robert Jeske has estimated the proximity for materials to be considered local around 35 km (Jeske 2003) or 25 km (Jeske 1989) based on the location of outcrops as well as landscape features. It is unlikely that people would
have traveled much farther than this for raw materials on a regular basis. The bedrock locations of materials classified as local to Aztalan fall within a 40 km catchment of the site. While this may be a greater distance than Jeske suggested, a 40 km catchment has been used for nearby Oneota sites because raw materials that may outcrop 5 km outside of the 35 km buffer could also all have been available in the glacial till locally (Sterner 2018). Local raw material types at Aztalan include Galena chert, Limestone, Lower Prairie du Chien Chert (Oneota Formation), Upper Prairie du Chien Chert (Shakopee Formation, oolitic), Quartzite, Rhyolite, and Silurian Chert (Niagara Formation) (Table 4.3-4.4). Of the total artifacts (tools included) made from locally available raw materials 15% are good quality, 48% are fair quality and 37% are poor quality. Also, 57% of artifacts made of local raw materials are heat treated and 57% were cortex-free. The most prevalent local raw material types within the debitage and tool assemblages are Galena chert followed by Silurian chert. Galena chert can be obtained from continuous bedded formations or as isolated nodules. It is a medium-fine to fine grained chert typically gray or light gray with dark mottles and a dull to satiny luster however when heat treated, color mat change to pale red, reddish brown or medium gray with a satiny to glossy luster (Winkler et al. 2009; Morrow and Behm 1987). Galena chert is found south-central and southwestern Wisconsin, northwestern Illinois, southeastern Minnesota, and northeastern Iowa with several formations sharing a broadly similar character (Winkler et al. 2009; Morrow and Behm 1987). A common characteristic of galena chert is the presence of numerous crushed fossil bits and fossil borings that appear as dark spots or circles (Morrow and Behm 1987). Silurian chert refers to several similar varieties of white to very light gray chert with a frequent chalky luster found in northeastern Iowa, northern Illinois, and eastern Wisconsin (Morrow and Behm 1987). Fossils commonly found in Silurian chert include small crinoid columns, small solitary corals, and
sometimes small brachiopods (Winkler et al. 2009; Morrow and Behm 1985; Ferguson and Warren 1992). When heat treated, Silurian chert may turn a grayish to orangish pink color and may achieve a satiny luster (Morrow and Behm 1987).

Non-local material types comprise 20% of the debitage and 21.3% of the entire assemblage. These types include; Basalt Burlington chert, Baraboo Quartzite, Barron County Pipestone, Cochrane chert, Dongola chert, Maquoketa Formation Chert, Mill Creek chert, Moline chert, Platteville Formation Chert, Quartz, St. Genevieve chert and unknown varieties of Silicified Sandstone (Table 4.3-4.4). Of all the artifacts made of non-local raw materials 40% are good quality, 21% are fair and 39% are poor. However, Basalt is usually graded as poor because it is not desirable for producing chipped stone tools but instead is desirable for making ground stone tools. If the large amount of Basalt present in the debitage is excluded, then 58% of the artifacts made from non-local materials are of good quality, 30% are fair and only 11% are poor quality. The most prevalent non-local raw material types among the debitage are Burlington chert and unknown varieties of Silicified Sandstone. Burlington chert is a fine to medium grained material with a dull to satiny luster that ranges from white to light gray in color and is found in southeastern Iowa, west-central Illinois, and northeastern Missouri (Morrow and Behm 1987; Rick 1978; Kelly 1984). Typically, Burlington chert is a good quality material that when heat treated, often turns a pink to orangish or reddish color and achieves a satiny to glossy luster (Morrow and Behm 1987). Of all the artifacts in the assemblage made from Burlington chert, 88% were good quality and 12% were determined to be fair quality. Also, 90% of the Burlington chert artifacts are cortex-free and 62% show no evidence of heat-treatment. Silicified sandstones, also known as orthoquartzites, are sedimentary rocks formed when silica dissolved in groundwater cement the grains within sandstone together allowing for conchoidal fracture of the
stone (Winkler et al. 2009; Behm 1998). There are several silicified sandstone outcrops and quarry sites located near one another in western Wisconsin and because of the overlap in color and texture, it is often difficult to distinguish between the various types (Winkler et al. 2009). Because these types are so similar in quality and texture a catch-all “unknown silicified sandstone” category is used here to classify any silicified sandstone in the assemblage. Silicified sandstone ranges from a course to medium texture, has a sugary luster and displays a wide range of colors including; white, pale orangish brown, light brown, brown, yellow, red and lavender (Morrow and Behm 1987). Heat treatment of silicified sandstone can weaken silica cementing the sand grains together, ultimately ruining the material for tool making (Morrow and Behm 1987; Winkler et al. 2009). Of all the artifacts in the assemblage made from unknown varieties of silicified sandstone, 53% were of good quality and 42% were of fair quality. Also, 95% of the artifacts made from unknown varieties of silicified sandstone showed no signs of heat alteration and 91% were cortex-free.

The remaining 21% of the debitage consists of unknown cherts or otherwise unidentifiable raw material types which could not be determined as either local or non-local. Of all the artifacts made from unknown raw materials, 42% of the unknown raw materials were cortex-free and 59% showed no sign of heat alteration. Also, of all the artifacts made from unknown raw materials 51% were of poor quality, 42% fair quality and only 7% were of good quality.

Overall quality of raw materials was either characterized as good, fair or poor. Raw material quality refers to the flaking quality of the raw material and is often determined by the size and number of inclusions, grain size, and fracture plains (Jeske 2014). The debitage consisted of 43% poor quality materials, followed closely by materials characterized as fair (41%) and 16% of the raw materials were of good quality (Table 4.5). Of the fair quality debitage, 53% was heat treated and 38% possessed some amount of cortex. Of the Good quality materials 59% were heat-treated and 16% had cortex. Finally, of the poor-quality materials 37% were heat treated and 58% possessed some cortex.

Chipped Stone Tools

The lithic assemblage from the 1984, 2011 and 2013 UWM field schools at the Aztalan site contains a total of 200 chipped stone tools weighing a total of 488.22g (Table 4.6). Therefore, the debitage to tool ratio is a low 6:1. The significance of the debitage to tool ratio will be discussed later in this thesis. Of the 201 tools in the UWM Aztalan assemblage, 70% were cortex-free and 58% displayed some evidence of heat treatment (Table 4.6). Generally, chipped stone tools in the UWM Aztalan assemblage are small and complete tools have a mean length of 21.74 mm, a mean width of 15.31mm, a mean thickness of 5.27mm and a mean weight of 2.34g.

Tools were categorized into one of seven types of basic tool form; edge or functional unit only, unifacial, bifacial, multifacial, blade, and unknown. Of the 200 total tools 70% were categorized as edge only tools which are expedient tools that show evidence of retouching or use-wear only on the edges (Table 4.6). Bifacial tools make up 18% of the tool assemblage while
multifacial tools make up 3.5% and unifacial tools make up 3%. Additionally, 3.5% of the assemblage consists of small pseudo blades which are actually blade-like flakes removed from small cores likely through using bipolar reduction (Jeske 1992). While there were not any nonfacial tools identified in the assemblage, 2% were determined to have unknown basic forms (Table 4.6).

While lithic technology of earlier periods was based largely on formal, highly standardized tool types, the majority of chipped stone tool assemblages from Late Woodland and Mississippian contexts consist of expedient flakes that are usually struck from amorphous cores (Parry and Kelly 1987:287; Koldehoff 1987) Unsurprisingly then, the most common tools (63%) observed in the UWM Aztalan assemblage are utilized or retouched pieces of debitage that were probably discarded soon after use (Andrefsky 1994). In all, these flake tools are made from 59% local raw material types, 28% non-local and 13% are of unidentified raw material types. Raw material quality for these tools are 42% fair, 37% good and 21% poor quality. Also, 60% of the flake tools show evidence of heat treatment and 69% of these tools are cortex-free.

Additionally, 10 irregular cores or core fragments with multifacial or unknown basic forms were identified within the assemblage. The irregular shape of these cores is due to flakes having been removed from different directions through bipolar reduction. Cores in the assemblage consist of 70% local Galena and Silurian cherts and 30% non-local Burlington chert. available fair to poor quality raw materials. The most prevalent local raw material among the cores is Galena chert and the only non-local raw material among the cores is good quality, non-local Burlington chert. Overall cores are made from 40% good quality raw material, 40% poor quality and 20% fair quality. Also, 45% of the cores display some evidence of heat treatment and 46% are cortex-free. Similarly, 55% of the bipolar flakes were made from poor quality raw
material and most of the bipolar flakes displayed some amount of cortex and showed signs of heat treatment. Interestingly, none of the non-local Burlington chert cores show any evidence for heat treatment but 71% of the cores made from local raw materials do show evidence of heat treatment. One of the Burlington chert cores appears to have been retouched and used as a tool after it was no longer useful as a core. Also, these cores are generally not very large with an average weight of 15.16 grams. Core size, combined with the presence of cortex on most of the cores suggests a pattern of conserving non-local good quality raw materials while opportunistically utilizing poorer quality local raw materials that were probably mostly procured from glacial till or riverbed deposits and then heat treated to improve the quality. The use of bipolar reduction combined with the heat treatment of local raw materials suggests that the residents of Aztalan were using raw materials efficiently because they did not waste time heat treating good quality materials, instead they tried to improve the value of less expensive raw materials.

Formal tool types identified in the UWM Aztalan assemblage include 1 Scottsbluff point, 19 Madison Triangular points, one Humpback biface, three Cahokia side notched points, One Nodena elliptical point, One Late Woodland Side Notched point, and two scrapers. Also, there are three Mill Creek chert hoe chips present in the assemblage that display a glossy polish from heavy use.

Scottsbluff

Scottsbluff points are straight stemmed, lanceolate shaped bifaces with slight shoulders, usually exhibiting a transverse parallel flaking pattern (Justice 1987; Ritzenthaler 1967;
Goldstein and Osborn 1988). Scottsbluff points are widely distributed throughout the plains region as well as parts of the Midwest and are diagnostic of the late Paleo-Indian and Early Archaic cultural periods (Goldstein and Osborn 1988). The Scottsbluff point in the UWM Aztalan assemblage is made from good quality, heat-treated, locally available Galena chert. It is nearly complete; however, it has what appears to be an impact fracture near the distal end. This point is 62.77 mm long, 9.83 mm thick, 21.65 mm wide, weighs 14.28 grams and was found during the 2011 field season in the riverbank area of the site at 42 cm below datum (Fig 4.1).

Fig. 4.1: Scottsbluff point from UWM Aztalan assemblage (Lot # 2011-20.0278.1)

*Madison Triangular*

The most common formal tool type in the UWM Aztalan assemblage is the Madison Triangular point. Madison triangular points are characteristically unnotched, straight or nearly straight sided triangular tools with their maximum width at the base (Perino 1968; Justice 1987;
Boszhardt 2003). These points may have bifacial, unifacial or edge-only basic forms (Sterner 2012). Dates for the Madison point type range from about A.D. 800 to A.D. 1350 and they are typical of Late Woodland and Mississippian cultural phases across eastern North America (Justice 1987). In all, 53% of the Madison points in the assemblage are made from local raw materials. However, various types of non-local silicified sandstones ($n=9$) are the most prevalent raw material type among all the Madison points in the assemblage. Of the Madison points in the assemblage, 63% ($n=12$) are complete and 37% ($n=7$) are broken. Also, 47% of the Madison points show some evidence of heat treatment or burning. The mean length of the Madison points in the UWM Aztalan assemblage is 22.2 mm, the mean width is 18 mm, the mean thickness is 4.3 mm and the mean weight is 1.6 grams (Fig 4.2).

![Selected Madison points from UWM Aztalan assemblage](image)

*Fig. 4.2: Selected Madison points from UWM Aztalan assemblage (Top to bottom, left to right, lot #s 2011-20.003.1, M-84-1278.1, M-84-1145.1, M-84-1103.1, M-84-1013.1, M-84-1013.2, M-84-2001.6)*
While humpback bifaces are typologically included with Madison triangular points, these artifacts tend to be more crudely made than other Madison triangular points (Jeske 1992; Sterner 2012; 2018). Also, they are found so infrequently at Mississippian sites that many researchers do not consider them to be a separate morphological category (Jeske 1992a). Humpback bifaces have been defined as “bifacially worked, more-or-less triangular pieces, with many step fractures that result in a hump on one face” (Jeske 1992a:470). These points are typically the products of the bipolar reduction of poor quality cherts and have been interpreted as an efficient response to insufficient access to good quality local raw materials (Jeske 1992a). While they have been interpreted morpho-functionally as unfinished triangular points, scrapers, knives, and triangular preforms, Jeske has argued that “humpbacks should not be viewed as a functional class at all, but as a manufacturing type” (Brown 1961; Fowler 1952; Munson and Munson 1972; Jeske 1992a:470; Sterner 2012; 2018). These points are considered as a manufacturing technique and not a functional class is because the functionality of these tools is not well-understood because they appear to have been used for multiple purposes including as knives, projectile points and scrapers (Jeske 1992a; Sterner 2012; 2018). One humpback biface is present in the UWM Aztalan assemblage. This point was examined by Dr. Katherine Sterner using an Olympus BH-1 upright microscope with reflected light fluorescence attachment at both 100x magnification and 200x magnification. She found evidence of meat polish in one location that is consistent with use as a projectile point (Sterner personal communication 2018). Humpbacks are typically found at late prehistoric sites in northwest Indiana, northern Illinois, southern and central Ohio and southwest Pennsylvania, but are less common in Wisconsin lithic assemblages (Munson and Munson 1972; Jeske 1992a; Sterner 2018). The humpback in the UWM Aztalan assemblage was
found in test unit 12 in the riverbank area at 32cm below datum. It is 31.61mm long, 17.5mm wide, 6.82mm wide and weighs 2.67 grams and is made of fair quality, unheated, cortex-free Galena chert.

![Fig. 4.3: Humpback biface from UWM Aztalan assemblage (Lot# 2011-20.0249.1)](image)

_Cahokia Side Notched_

There is one complete Cahokia side notched point and two Cahokia side notched fragments in the UWM Aztalan lithic assemblage. One point was found in the northeast woodlot area, one in the northeast mound area and one in the 1984 ravine. One is made from fair quality Silurian chert, one is made from good quality Prairie du Chien chert and one is made from good quality Burlington chert. Cahokia side notched points are small triangular arrowheads which, as the name implies, are notched on the sides but sometimes will also be notched at the base (Fig 4.3). There are four subclasses: Cahokia double-notched, Cahokia triple-notched, Cahokia multiple-notched and serrated (Scully 1951; Justice 1987; Goldstein and Osborn 1988; Boszhardt 2003), though, all the Cahokia point bases in this assemblage resemble the Cahokia double notched type. Cahokia points are diagnostic of early, middle and late Middle Mississippian
cultural phases and have been found at most sites that were associated with the Cahokia site (Perino 1968; Justice 1987; Goldstein and Osborn 1988). Overall, 75% of the Cahokia points in the assemblage are made from locally available raw material types and 75% show evidence of heat treatment.

![Cahokia points from UWM Aztalan assemblage](image)

Fig. 4.4: Cahokia points from UWM Aztalan assemblage (left to right, lot# M-84 1402.1, 2011-20.0185.3, 2013-106.0047.1)

**Nodena Elliptical**

Nodena Elliptical points are described as willow-leaf shaped bifaces with an excurvate, elliptical form that are either bi-pointed or have a rounded base (Bell 1958; Justice 1987:230; Naumann 2008:115). They have been recovered from a few sites in southern Wisconsin and as far south as Florida and are diagnostic of the late Mississippian and proto-Historic periods, A.D. 1400-A.D. 1700 and after (Justice 1987). The Nodena Elliptical point in the UWM Aztalan assemblage was recovered from the northeast mound precinct and is made from fair quality, locally available Silurian chert that shows no evidence of heat treatment or cortex. It is 39.25mm long, 15.06mm wide, 5.7mm thick and weighs 2.98 grams (Fig 4.4).
Late Woodland Side Notched

Late Woodland Side Notched is the name of a catch-all category used to describe a side-notched projectile variety often recovered from sites associated with Late Woodland or Middle Mississippian cultural components (Goldstein and Osborn 1988; Perino 1971; Naumann 2008). These points are generally small triangular points with straight to convex sides that have been notched one quarter of the way up and typically have a straight or concave base (Naumann 2008:116). The Late Woodland side notched point in the UWM Aztalan assemblage is made from a fair quality unknown chert type and has been burned and fire cracked into four pieces that were re-fitted by the author during data collection (Fig 4.5).
Mill Creek Hoe Chips

Mill Creek chert is found in the form of large nodules in the Mill Creek Valley in Southern Illinois just to the East of the Mississippi river, not very far downriver from Cahokia (Cobb 2000). Colors of Mill Creek chert vary from predominately brown to grey or blue-grey and it is of a grainy texture that displays little or no luster (Cobb 2000). Stone hoes made from Mill Creek chert are recognized as one of the most widely distributed items in prehistoric times (Cobb 2000; Winters 1981). The distribution of Mill Creek hoes extended from the northernmost site at Aztalan, as far east as Ohio, as far south as Mississippi, and as far west as Oklahoma, an area encompassing 200,000 square miles (Winters 1981). These tools appear to have been highly prized items in the Middle Mississippian world. Large caches of unused hoes are commonly found at mound centers throughout the American Bottom and have also been found hidden along house walls and in abandoned storage pits (Milner et. al 2010). Examples of Mississippian stone hoes vary in shape but generally fit into three main groups; oval, flared, and side-notched (Cobb 2000; Milner et. al 1984). While variations of this type exist, Mill Creek stone hoes are generally considered to have been multi-purpose digging tools due to their size, and presence of a mirror-like gloss on the bit-end of used pieces (Cobb 2000; Milner et. al 1984). While there are no
complete hoes present in the UWM Aztalan lithic assemblage, there are three Mill Creek chert flakes present that do display the characteristic mirror-like gloss created by digging in soil (Fig. 4.6). Images were captured of the polish on one of these Hoe chips by Dr. Katherine Sterner using an Olympus BH-1 upright microscope with reflected light fluorescence attachment at both 100x magnification and (Fig. 4.7b) 200x magnification (Fig. 4.7a). Relying heavily on an intensive maize agriculture, Middle Mississippian groups would have benefitted greatly from an efficient and dependable standardized tool type that could be used to maintain fields and harvest crops. Not only that, these tools would have been valuable for more than just agricultural purposes, they would have also been used for several other tasks including digging wall trenches for houses, and of course the construction of large platform mounds (Cobb 2000). As previously mentioned in this thesis, Barrett reported finding three of these tools at the site as well as two quartzite fragments resembling this hoe form which he interpreted as being a likely attempt “to translate the southern flint spade into materials more commonly found in the Aztalan region” (Barrett 1933:272) Additionally, the presence of one Madison point made from Mill Creek chert in the UWM Aztalan lithic assemblage suggests that people at Aztalan used this expensive raw material economically, choosing to recycle it rather than discard it.

Fig. 4.7: Mill Creek chert hoe chips from UWM Aztalan lithic assemblage (Lot #s 2011-20.0318.3, 2011-20.0327.1, 2013.106.0071.1)
Scrapers

While the name scraper can be subjective, scrapers have been defined as “a unifacial or bifacial piece with edges modified by flaking and edge angle greater than 75 degrees” (Sterner 2018:144). There were only two chipped stone tools characterized as scrapers in the UWM Aztalan assemblage (Fig. 4.8). Both were recovered from test unit 15 in the northeast mound area. One scraper appears to have been flaked and used on the side and is referred to as a side-scraper. This side-scraper is made from a poor quality, indeterminate raw material type and it is 32.8mm long, 21.49mm wide, 16.54mm thick and weighs 9.42 grams. The second scraper in the assemblage is an odd artifact. It appears to be a small pebble that had one side broken off flat and
was then water rolled for some amount of time. The steep end of the pebble has been flaked and used. This small end scraper is 20.14mm long, 18.03mm wide, 9.58mm thick and weighs 4.16 grams.

In 1962, Robert Hall published a table containing values for what he termed an “endscraper index” (Hall 1962b:139). Hall pointed out that Oneota sites, although varying widely, tended to have much higher indices than Mississippian sites. Curiously, Aztalan had the lowest ratio of all based on a total of two reported end scrapers. Hall also noted that “the proportion of end scrapers relative to triangular points increases toward recent times and toward the Plains area” (Hall 1962a:121-122). Richards reviewed Hall’s comment and noted that as of 1992, there were still only four endscrapers in all of the reported assemblages from Aztalan (Richards 1992:51). Boszhardt and McCarthy (1999) revisited Hall’s original insight and suggested that the high scraper frequencies found at sites in the Plains region and lower frequencies at Oneota sites in eastern Wisconsin and northeastern Illinois reflects a correlation between high numbers of scrapers at archaeological sites and bison hunting (Boszhardt and McCarthy1999). However, Sterner reported that the scraper/point indexes at five La Crosse locality sites varied greatly and “that the correlations between geography, scraper production, and bison processing are not clear cut” (Sterner 2018:155). In addition, Sterner has shown that both formal and informal tools not morphologically similar to classic scrapers were used to scrape a variety of materials (Sterner and Jeske 2017). At any rate, there is clearly a low frequency of scrapers in the UWM Aztalan assemblage. Matthew Warwick (2002) conducted a diachronic analysis on faunal remains from Stratum 5 and Stratum 11 from the 1984 Ravine area excavations. Results indicate a subsistence pattern with a dominance of mammals, predominantly white-tail deer (Warwick 2002). Although not statistically significant, a trend
toward increased exploitation of fish between Late Woodland and mixed contexts was observed. Jennifer Picard (2013) conducted a diachronic analysis of Late Woodland and Middle Mississippian floral assemblages at Aztalan (Warwick 2002). Picard reported that “the residents of Aztalan focused on horticultural, and arguably agricultural, resources such as maize and squash, with heavy supplementation with hickory nuts.” (2013:238). Moreover, Picard also argues that the importance of nutshell appears to decrease and the importance of maize increases over time (Picard 2013). Consequently, it is not surprising that as maize agriculture and fish consumption intensified at Aztalan, fewer scrapers would have been produced by the inhabitants.

Fig. 4.9: Scrapers from UWM Aztalan lithic assemblage. Side-scraper (Right) (Lot# 2013-106.0111.1) End-scraper (Left) (Lot# 2013-106.0053.2)
Chipped Stone Tool Raw Materials

Like the debitage, overall there is a wide variety of raw materials represented in the UWM Aztalan chipped stone tool assemblage (Table 4.7). Also, locally available raw materials or stone that would have been available in glacial deposits, dominate the assemblage (60%) (Table 4.8). Like the debitage, the most common local raw materials are Galena chert followed by Silurian chert and the most common non-local raw materials are Burlington chert followed by unknown varieties of Silicified Sandstone. It is notable that St. Genevieve chert is also present within both the debitage and tool assemblages. St. Genevieve chert, also known as Root Beer chert, is a fine grained banded chert with ranges of reds, browns, grays and semi translucent whites that is found in southeastern Missouri and southwestern Illinois (Kelly 1984). In the American Bottom, St. Genevieve chert is known to have been utilized more heavily during the emergent Mississippian period, gradually being replaced in importance by Burlington chert over time (Milner et al. 1984; Kelly 1984). Of all the artifacts made from St. Genevieve chert, 95% were cortex-free. Only one flake tool and none of the debitage made from St. Genevieve chert displayed any amount of cortex. Similarly, 90% of the chipped stone tools and debitage in the assemblage made from Burlington chert are cortex-free. Unsurprisingly, this suggests that these non-local materials came to Aztalan in reduced form and were not transported as cobbles upriver from Missouri to Wisconsin.

Unlike the debitage, the overall quality of raw materials used for the chipped stone tools was found to be mostly of fair quality or good quality while a minority of the tools were made from poor quality raw materials (Table 4.9). This is likely because higher quality materials flake
more easily than poor quality materials and therefore can produce more flakes with usable edges that would have been desirable to use as expedient tools before being discarded.

*Summary*

Overall, lithic technology at Aztalan adheres to the general pattern of chipped stone tool production and use that is common for Late Woodland and Middle Mississippian sites across the eastern United States (Koldehoff 1987). Generally, the UWM lithic assemblage suggests a focus on efficiency and the economizing of lithic raw materials. Efficiency refers to the careful use of time and energy in tool production while economy refers to the strategic management of resources to obtain the highest yields at the lowest costs (Jeske 1992, 1989; Sterner 2012). For example, the high percentage of edge-only tools (70%) in the UWM Aztalan lithic assemblage suggests a focus on the efficient use of time and energy through the production of expedient...
tools. Also, tools in the UWM Aztalan assemblage are generally small. Tool size usually reflects the availability of raw materials because “the scarcity of high-quality materials or restriction in the size of the available materials will result in smaller, less well-made tools” (Behm 1998:26). The high frequency of heat treatment among tools and debitage (49%) also suggest a focus on the economical use of resources and a concern with improving the quality of their raw materials so that the most value may be obtained from it (Rick 1978; Lurie 1989). The low flake-to-tool ratio of 6:1 is also evidence of economizing behavior regarding lithic technology because it shows that raw materials were used conservatively at Aztalan. This is not surprising considering that there are not any good nearby sources of chert except poor quality materials available in glacial deposits and riverbeds. Good quality or non-local raw materials can be considered expensive at Aztalan because the cost of time and energy for procurement and use are high (Jeske 1989). It is evident that the residents of Aztalan used expensive raw materials differently than poorer quality raw materials to produce chipped stone tools. The flake-to-tool ratio for non-local raw materials is 2:1 and it is 7:1 for local raw materials. Likewise, the flake-to-tool ratio for good quality raw materials is 2:1, 6:1 for fair quality materials, and 11:1 for poor quality raw materials. This suggests that tools made from expensive, good quality non-local materials were likely transported to the site as completed tools and were not formed on site.

Intensity of tool use also shows that chipped stone tools were used efficiently at the site. In total, 40% of the tools are broken, 55% were whole and completeness could not be determined for the remaining 5%. This suggests that tools were used until they failed rather than getting discarded whole. Intensity of use can also be measured by the number of functional units per tool. In total, 7% of tools showed no used edges or functional units, 40% showed one, 28% showed two, 22% showed three and 3% showed evidence of four used edges (Fig 4.10). This
suggests that most tools were used repeatedly before being discarded. Also, “Energy input into tool manufacture may be measured by the amount of cortex left on tool surfaces” (Jeske 2002:103-104). Since 70% of the tools showed no evidence of any cortex, it is reasonable to say that the residents of Aztalan put a moderate to high amount of energy into the production of chipped stone tools.

Chapter 5:
Discussion

*Intra-site Spatial Analysis*

The layout of the Aztalan site is very similar to other Middle Mississippian towns and is believed to represent the Mississippian social structure and reflect the Mississippian belief system (Birmingham and Goldstein 2006). Chipped stone materials in the UWM Aztalan lithic assemblage were excavated from five distinct areas of the site; the plaza, the NE woodlot, the NE mound, and two areas of the ravine midden that stretches along the riverbank (Fig. 5.1). To gain a better understanding of how the use of lithic technology may have varied across the site, lithic data from these five areas are compared. Table 5.1 shows quantities and percentages of debitage by site area and table 5.2 shows quantities and percentages of chipped stone tools by site area.

Plaza

The Plaza area (Fig. 5.3) consists of about three hectares in the center of the enclosure and it is believed that like many Mississippian towns, it was kept free of structures so that it would have been an open space that could be used for ceremonies and other gatherings (Goldstein and Freeman 1998; Goldstein and Richards 1991). During excavations in the plaza area in the 1960s, Joan Freeman noted that many of the features in this area were truncated and that due to modern farming of the site, much of the material in the plaza had washed downslope to the riverbank.
Excavations in the midden area along the riverbank in 1984 by UWM (Fig. 5.1) showed deposits of soils that had washed down from upslope (Kolb 1985). Also, excavations in the plaza area during 1984 “yielded evidence of a Late Woodland structure which... makes it seem likely that the plaza was not always a plaza” and suggests that the layout and structure of Aztalan could have changed over time (Goldstein and Freeman 1998:232). UWM excavations in 1984 were placed in the northwest portion of the plaza and were “designed as a geomorphic test trench to recover information on soils and sediments presumably responsible for the colluvial deposits occurring downslope near the river” (Richards 1992:167). However, these excavations encountered a post mold and pit features complex beneath the plow zone that Richards (1985, 1992) assigned to a pre-Mississippian occupation based on the absence of Mississippian pottery and a date of 870 B.P.±50 (cal. 2-sigma range of A.D. 1039-1257). A plan view map of this feature complex is shown in Figure 5.3 and a plan view photo of Plaza Unit E is shown in Figure 5.4. The plaza area lithic assemblage contains 134 pieces of debitage and 27 chipped stone tools (Table 5.1a-b). The flake-to-tool ratio is 5:1 in the plaza area. Three Madison points, two pseudo-blades, one uniface fragment, and 21 flake tools were recovered from the plaza area. Tools from the plaza area are an even 44% whole, 44% broken and completeness could not be determined for the remaining 12%. Of all the total chipped stone artifacts from the plaza area 50% are made of local raw materials and 34% are made of non-local materials. The most common local raw material is Galena chert (17%) and the most frequently occurring non-local material is St. Genevieve chert (6%). Like other areas of the site, most of the raw material in this area is either fair quality (48%) or poor quality (27%), does show some evidence of heat treatment (67%) and does not display any amount of cortex (60%).
Fig. 5.2: Location of the Plaza area (Birmingham and Goldstein 2006:65 Fig. 4.14)
Fig 5.3: Planview map of 1984 plaza area feature complex (Richards 1992:168 Fig. 4.22)
In 1984, UWM archaeology field school students led by Dr. Lynne Goldstein systematically excavated in a “distinct area of site along the river which was used as a garbage dump” (Goldstein and Freeman 1998:232). Figure 5.6 is a photo of the soil profile of this midden area and Figure 5.7 is a plan map of the 1984 Ravine area excavations (Richards 1992). Barrett described the riverbank midden as “a visible berm running 600 feet north-south along the west bank of the crawfish river” and he estimated that the midden was around eight feet deep and 40 feet wide (Richards 1992:126; Barrett 1970). The strategy of the 1984 UWM excavations was to
cross-trench the midden and expose a soil profile perpendicular to the deposit (Richards 1992). The UWM Aztalan lithic assemblage contains 401 pieces of debitage and 54 chipped stone tools excavated from the 1984 Ravine area (Table 5.1a-b). There is thus a flake-to-tool ratio of 7:1 in the 1984 riverbank area. Tools from the 1984 ravine area include seven Madison points, one Cahokia side-notched point, one unknown biface, four biface fragments, three pseudo blades, three cores, one uniface and 34 flake tools. Tools in this area were 61% whole, 33% broken and completeness could not be determined for the remaining 6%. Of the total chipped stone artifacts from the 1984 Ravine area 74% are made of local raw materials and 11% are made of non-local materials. The most common local raw material is Galena chert (40%) and the most prevalent non-local materials is Burlington chert (4%). Most of the raw material in this area is either fair quality (42%) or poor quality (37%), does show some evidence of heat treatment (52%) but does not display any amount of cortex (57%).

Excavations in this midden area have provided evidence of a stratigraphically discreet layer solely associated with Late Woodland culture (Stratum 11) under deposits containing mixed Late Woodland and Middle Mississippian materials (Fig. 5.6). Stratum 11 contained 38 pieces of debitage and three chipped stone tools. Tools from stratum 11 include one core tool made from unheated, good quality Burlington chert, one utilized flake made from good quality St. Genevieve chert, and one utilized flake made from heat treated, fair quality Galena chert. Of all the chipped stone artifacts from stratum 11, 7% are made from non-local raw material types and 75% local raw material types. Also, 51% of chipped stone artifacts from stratum 11 were of poor quality, 39% were fair quality, 10% good quality, 54% showed some evidence of heat treatment and 54% possessed some amount of cortex. Raw material types found in Stratum 11 are tabulated below in Table 5.3.

Fig. 5.5: 1984 Ravine Excavation Profile (photo from Richards 1992:140 Fig.4.10, revised by J. Richards)
Fig. 5.6: Planview map of 1984 Ravine area excavations (Richards 1992:139 Fig. 4.9)
In 2011 and 2013 Dr. John Richards led excavations in other areas of the riverbank midden. Excavations during 2011 into the Riverbank area provided evidence of a filling episode that is believed to have been an attempt to increase the amount of habitable area within the residential portion of the site (Richards and Zych 2011). In one area of the midden, re-deposition of upslope sediments containing debris dating to the Mississippian settlement of Aztalan overlay a deposit of aboriginal “buckshot” fill (Richards and Zych 2011) (Fig. 5.10). In another area of the riverbank, a test unit revealed an intact lens of ash and charcoal, designated as Feature 8 (Fig. 5.9). Excavated before the end of the 2011 field season, the northwestern half of Feature 8 produced a very rich assemblage of material culture including lithics, sheet copper fragments, grit and shell tempered pottery as well as an unusually wide variety of floral and faunal specimens including kernels of maize that have been submitted for AMS radio carbon dating and produced a median probability date circa A.D. 1106 (Picard 2013). This date, combined with the data from the material culture, has placed Feature 8 in the early Mississippian phase of the site’s occupation. Dr. Richards returned to Aztalan during the 2013 field season with the major goal of returning to the riverbank midden area, removing the 2011 backfill, and recovering the remaining southeastern portion of Feature 8. Figure 5.8 is a photo of these excavations taken during the 2013 season and Figure 5.9 is a plan map showing Feature 8 and 2013 palisade excavations over Barrett’s map of Section V-A, enclosure 30 (modified from Barrett 1933: Sec. Plat. V-A) (Picard 2013). The UWM Aztalan lithic assemblage contains 526 pieces of debitage and 82 chipped stone tools excavated from the riverbank area. There is thus a flake-to-tool ratio of 6:1 in the riverbank area. Of all the tools from the riverbank area, 52% were whole, 44% were broken and completeness could not be determined for the remaining 4%. More chipped stone tools and debitage came from this area than any other
area (Table 5.1a-b). Tools found in the riverbank area include one Scottsbluff point, eight Madison points, one Cahokia side-notched point, one Late Woodland side-notched point, one unknown biface, eight unknown biface fragments, one pseudo-blade fragment, five cores, four uniface fragments, three Mill creek hoe chips, one scraper and 48 flake tools. There is a large amount of non-local basalt debitage that was recovered from this area. Much of this Basalt debitage displayed evidence of grinding, pecking and some showed possible evidence of bipolar reduction. It is likely that this debitage represents the production, use or maintenance of ground stone tools such as adzes or Mississippian celts. One broken Mississippian celt was recovered from the Riverbank area from Feature 8 and a celt fragment was recovered from the northeast mound area as well. Of the total chipped stone artifacts from the riverbank area 51% are made of local raw materials and 31% are made of non-local materials. The most common local raw material is Galena chert (23%) and the most prevalent non-local materials are Basalt (15%) and Burlington chert (7%). Excluding the basalt, most of the raw material in this area is either fair quality (36%) or poor quality (33%), does not show any evidence of heat treatment (59%) and does not display any amount of cortex (59%).

Feature 8 contained a total of 90 pieces of debitage and four tools. Tools from feature 8 include one Mill Creek chert hoe chip and three utilized flakes made from local raw materials. Of all the chipped stone artifacts recovered from feature 8, 68% are made of non-local raw material types, 26% show some evidence of heat treatment and 21% have some amount of cortex (Table 5.4). There is a large amount of non-local, poor quality basalt debitage in Feature 8. Interestingly, 18% of this Basalt debitage shows evidence of grinding or pecking on the ventral surface. If this Basalt is excluded from the analysis, then 58% of the chipped stone artifacts in Feature 8 are made from fair quality raw materials, 31% poor quality, 11% good quality and 53% then are heat treated.

MPM Excavations (1919-1932) and UWM Excavations (2011-2013)

Fig. 5.8: Map showing Feature 8 and 2013 riverbank excavations over Barrett’s map of Section V-A enclosure30 (modified from Barrett 1933: Sec. Plat. V-A) (Picard 2013:109 Fig. 3.5)
Fig. 5.9: Soil profile of TU2 from 2011 UWM excavations in the riverbank area. Note buckshot fill in lower deposits.
Northeast Woodlot

The Northeast woodlot refers to an area within the northeast corner of the palisade north of the enclosed habitation area. This is an under-investigated area of the site and the 2011 UWM excavations represent the first investigations in this area. Preliminary analysis suggests the excavated context may represent a structure and habitation area but no culturally or temporally diagnostic materials were recovered (J. Richards, personal communication). A total of three, 1-x-1-m test units were excavated in the northeast woodlot area. Figure 5.11 is a photo of test units 11 and 13 from the 2011 UWM excavations in the Northeast Woodlot area. Excavations in this area produced only 62 pieces of debitage and 18 chipped stone tools. There is then a flake-to-tool ratio of 3:1 in the northeast woodlot area. Tools found in the northeast woodlot area include one biface fragment, one core fragment and 16 flake tools. Of the chipped stone tools from the northeast woodlot, 50% were broken, 39% were whole and completeness could not be determined for the remaining 11%. Of the total chipped stone artifacts from the northeast woodlot area 46% are made of local raw materials and 15% are made of non-local materials. The most common local raw material is Galena chert (23%) and the most prevalent non-local material in this area is Burlington chert (6%). Most of the raw material in this area is either fair quality (45%) or poor quality (35%), does show some evidence of heat treatment (58%) and does not display any amount of cortex (55%).
Fig 5.10: Test units 11 and 13 from 2011 UWM excavations in the Northeast Woodlot area
Northeast Mound and NE Mound Precinct

Another goal of the 2013 UWM field season focused on locating and identifying the extent of the northeast mound. The Northeast mound (Fig. 5.12) was a low rectangular platform mound located within the northeast corner of the domestic enclosure (Birmingham and Goldstein 2006; Zych 2013; Richards 2017; Richards and Zych 2018). Excavations into the mound in 1964 by the Wisconsin Historical Society (WHS) showed that the mound was built over a large structure (Zych 2013; Freeman 1986). It was determined that this structure had been re-built at least once and profiles of the mound illustrate that “it was constructed in a series of short-term episodes, including the formation of small internal-mound constructions; possibly earlier mounds” (Zych 2013:183; Freeman 1986). Based on historic accounts of Mississippian communities in the Southeast, this structure is believed to have functioned as a council house or temple (Birmingham and Goldstein 2006:61). Radiocarbon dates collected by UWM in 2013 from submound contexts suggest that construction of the mound took place during the early to mid-twelfth century AD (Picard and Richards 2014; Richards and Zych 2018:245). Figure 5.13 is a photo of the soil profile of TU 17 from the 2013 UWM excavations into the northeast mound. Figure 5.14 is a plan view photo of TU 18 from 2013 UWM excavations in the northeast mound precinct area. The UWM Aztalan lithic assemblage contains 78 pieces of debitage and 19 chipped stone tools excavated from the northeast mound area. There is then a flake-to-tool ratio of 4:1 for chipped stone artifacts from around the northeast mound. Tools from the northeast mound area include the Nodena point mentioned earlier in this thesis (recovered from a small pit feature located just off the west apron of the mound), three biface fragments, one pseudo-bladelet, one core, two scrapers, one graver and ten flake tools. Of the total chipped stone artifacts 69% are made of local raw material types and 23% are non-local. The most common local raw material is Galena chert (39%), the most prevalent
non-local materials are Burlington chert (10%) and unknown varieties of silicified sandstone (10%). Like the rest of the site, most of the raw material is either fair quality (48%) or poor quality (35%), does not show any evidence of heat treatment (59%) and does not display any amount of cortex (63%). Also, 79% of the tools in the northeast mound were complete and only 21% were broken.

Fig. 5.11: Location of Residential Area and Northeast Mound (Birmingham and Goldstein 2006:58 Fig. 4.7)

Fig. 5.13: Planview of TU 18 from 2013 UWM excavations in the northeast mount precinct area. The Nodena point was recovered from the dark stain near the center of the trench.
Intra-site Temporal Analysis

As previously mentioned in this thesis, a major goal of this project was to identify differences in the organization of lithic technology at Aztalan through comparing isolated Late Woodland context materials to mixed Late Woodland/Middle Mississippian context materials. Most archaeological deposits excavated at Aztalan contain mixed Late Woodland and Middle Mississippian artifacts; single component deposits are extremely rare. However, data used in this study was recovered from multiple distinct areas of the site that were created by discrete depositional events during different temporal periods and include two, pure, late Woodland assemblages. These areas include a Late Woodland living surface in the Plaza, and a Late Woodland discard deposit (Stratum 11) in the ravine midden excavated in 1984. Mixed Late Woodland and Middle Mississippian assemblages include data from the plow zone in the Plaza area, the northeast woodlot, other stratified midden deposits, a mixed context pit feature, and mound fill from the Northeast platform mound.

Late Woodland Context Lithics at Aztalan

This data includes data from artifacts in Stratum 11 in the ravine midden and all chipped stone tools and debitage recovered from below the plow zone in the plaza. In all, chipped stone data from discrete Late Woodland contexts at Aztalan include 16 tools and 88 pieces of debitage. Of all the chipped stone artifacts from these contexts, 58% were made from local raw materials, 10% non-local raw materials and 32% unidentified raw materials (Table 5.7). Table 5.5 shows the totals and percentages of raw material types for all chipped stone artifacts excavated from Late Woodland contexts. While the presence of St. Genevieve chert in Late Woodland contexts is surprising, it may be a result of bioturbation or plowing. Alternatively, it may reflect Late
Woodland participation in early Mississippian trade networks. In all, 64% of the artifacts from these contexts were heat treated and 49% displayed no amount of cortex. The quality of raw materials from Late Woodland contexts is mostly poor (44%) and fair (42%) with a small amount of good quality materials (14%).

**Mixed Context Lithics at Aztalan**

Mixed context data includes chipped stone artifacts from all other contexts except Stratum 11 in the ravine midden and below the plow zone in the plaza. Chipped stone data from mixed Late Woodland/Middle Mississippian contexts in the UWM Aztalan assemblage include 184 tools and 1,113 pieces of debitage. Of all the chipped stone artifacts from these contexts, 59% were made from local raw materials, 23% non-local raw materials and 18% were of unidentified raw material types. Table 5.5 shows the totals and percentages of raw material types.
for all chipped stone artifacts in the assemblage excavated from mixed contexts. In all, 47% of the artifacts from mixed contexts showed evidence of heat treatment. and 59% displayed no amount of cortex. Like materials from Late Woodland contexts, the quality of raw materials from mixed contexts is mostly poor (41%) and fair (40%). However, there appears to be more good quality raw materials (19%) present in the mixed contexts than in Late Woodland contexts.

While in small amounts, there appears to be a noticeable increase in the variety of non-local raw materials in mixed contexts than Late Woodland contexts. This may be due to differences in sample size, however it is interesting that southern materials such as Mill Creek chert and Moline chert show up only in mixed contexts. Moline chert is found in tabular form in the bluff slopes at the mouth of the Rock river in west-central Illinois (Morrow and Behm 1985; Springer 1982; Hendrickson 1996). Moline chert ranges from light gray to blue-black that usually follows a streaked color pattern and has a medium to medium-fine texture, a dull to satiny luster and often contains diagnostic dark spicular fossil inclusions (Morrow and Behm 1985).

Chapter 6:

Analysis and Interpretations

Statistical Analysis

Data from this project was submitted to statistical analysis by Dr. J. Patrick Gray, UWM Anthropology Department statistician, using the R software package. Statistical analysis was designed to investigate general questions about the lithic economy of the site as well as exploring questions related to spatial and temporal patterning of the lithic assemblage. A Chi-squared test of independence was used to assess the relation between targeted variables. Variables statistically significant at the .05 level were assessed for strength of relationship using the phi statistic for 2-way tables and Cramer’s V for larger arrays. Cramer's V for effect size was assessed as follows: 0.0 - 0.09: negligible; 0.10-0.29: low effect; 0.30-0.49: moderate effect; 0.50-0.69: substantial effect; 0.70+ very strong effect. Results of this analysis suggest that seven of the variables investigated do not appear to exhibit statistically significant relations. These variables are shown below in Table 6.1. Consequently, the seven examples not statistically significant at the .05 level are not considered in the following discussion but statistical tests for all variable associations are listed in Appendix 1.
In addition, although the Chi-squared test suggests a statistically significant relationship, the Cramer’s V values for three variables suggests the strength of the relationship is negligible.

These variables are listed in Table 6.2. Although these relationships may be negligible, they also point to certain trends that are present within the assemblage. First, there appears to be a relationship between raw material locality and period ($X^2 (1, N = 1363) = 7.9705, p < 0.0047547, V=0.087$). Local raw materials are found more often in Late Woodland contexts than in mixed contexts and non-local raw materials are found more often in mixed contexts than Late Woodland contexts. This suggests that there was an increase in access to non-local raw materials over time at Aztalan. There also appears to be a relationship between period and the presence of heat treatment ($X^2 (1, N = 1363) = 11.865, p < 0.000572, V=0.093$). Heat treatment is present more in Late Woodland contexts than mixed contexts. This suggests that heat treatment of raw materials decreased over time at the site. Finally, there is also a significant but weak relationship
between raw material locality and debitage form ($X^2 (1, N = 1152) = 9.8778, p <0.04, V=0.065$). Local raw materials are found significantly more as flakes than non-local raw material.

Ten variables are statistically significant at the .05 level and have low relationship strengths as measured by Cramer’s V (Table 6.3). The relation between cortex presence and raw material locality was significant ($X^2 (1, N = 1363) = 28.590, p <8.9466e-08, V=0.164$). Cortex is present more in local raw materials than non-local and is absent to a greater degree in non-local raw materials. The relationship between quality and presence of heat treatment was also significant ($X^2 (2, N = 1363) = 35.454, p <2.0015e-08, V=0.161$). Heat treatment is more common in fair and good quality raw materials than poor quality raw materials. Likewise, heat treatment is less common in poor quality raw materials than good or fair. There was a significant relationship between quality and debitage form ($X^2 (4, N = 1152) = 63.187, p <6.1973e-13, V=0.166$). Flakes are either good or fair quality more often than they are poor quality and flake-like pieces are typically of poor quality. Non-flakes are of poor quality more often than they are good or fair quality.
A significant relationship was observed between locality, which is whether the artifact is made from local or non-local raw material, and size category ($X^2 (6, N = 1294) = 52.881$, $p < 1.2398e-09$, $V=0.143$). Size one debitage is made from non-local raw material significantly more often than local. Also, size three debitage is made from local raw materials significantly more than non-local. Understandably, there is a relationship between size category and the presence of cortex ($X^2 (3, N = 1294) = 82.676$, $p < 0$, $V=0.253$). As one might expect, cortex is less common in size 1 and size 2 pieces of debitage and is present more often in size 4 pieces. There is also a significant relationship between the presence of heat treatment and site area ($X^2 (4, N = 1363) = 32.611$, $p < 1.4347e-06$, $V=0.155$). In the plaza and the 1984 Ravine, heat treatment is present significantly more than it is absent. While in the Riverbank area, heat treatment is absent significantly more than it is present. A significant relationship was also observed between locality and site area. Local raw materials were found significantly more than non-local materials in the 1984 ravine while non-local materials were found significantly more than local raw materials in the riverbank area. There was also a low strength relationship between site area and morpho-function. Edge-only tools were found in the Plaza area significantly more than bifaces. Also, hoe chips were found significantly more in the riverbank area. Period is a variable created to categorize artifacts as either from Late Woodland or Mixed contexts. There was a significant relationship found between period and debitage state ($X^2 (4, N = 1289) = 16.747$, $p <0.0021639$, $V=0.114$). Debitage is broken significantly more often in Late Woodland contexts than mixed contexts and debitage is complete significantly more in mixed contexts than Late Woodland contexts. Strangely, burned shatter is found significantly more in Late Woodland contexts than mixed contexts. There is also a significant relationship between debitage form and period ($X^2 (2, N = 1152) = 12.755$, $p <0.0016990$, $V=0.105$). Flakes are found
in mixed contexts significantly more than in Late Woodland contexts. Flake-like debitage and non-flakes are found in Late Woodland contexts significantly more than in mixed contexts.

Finally, there were two variables that were statistically significant at the .05 level and display moderately strong relationships based on Cramer’s V (Table 6.4). A moderately strong relationship was observed between raw material quality and cortex presence ($X^2 (2, N = 1363) = 128.29, p <0, V=.307$). As might be expected, cortex is absent significantly higher in good and fair quality raw materials than in poor quality raw materials. Likewise, cortex is present significantly higher in poor quality raw materials. Another moderately strong relationship was found between raw material locality and quality ($X^2 (2, N = 1363) = 90.380, p <0, V=.292$). Local raw material varieties are of fair quality significantly more often than non-local raw

Spatial Analyses Interpretation

Subtle differences and trends in the makeup of the chipped stone assemblages between different areas of the site appear to be a result of differences in depositional context. For example, the 2011 excavations into the Riverbank area deposits showed that in one area of the midden, re-deposition of upslope sediments containing debris dating to the Mississippian settlement of Aztalan overlay a deposit of aboriginal “buckshot” fill (Richards and Zych 2011). This filling episode is believed to have been an attempt to increase the amount of habitable area within the residential portion of the site (Richards and Zych 2011). This type of deposit is much different than that of the 1984 ravine area excavations which is a stratified garbage dump. Likewise, the deposits in the plaza and the northeast woodlot are interpreted as habitation areas while the lithic sample from the Northeast Mound excavations was recovered from mound fill. Unsurprisingly, there is a slightly higher flake-to-tool ratio in the 1984 ravine area and the riverbank midden areas than in the northeast woodlot, the northeast mound and the plaza. This
likely reflects the fact that the stratified midden consists of discard deposits and most of the Riverbank area contains re-deposited soils washed from upslope while the northeast woodlot and the plaza assemblages derive from habitation debris. Lithic materials in the fill of the Northeast Mound and surrounding areas may have derived from a variety of sources.

While proportions of good, fair and poor quality raw materials do not appear to differ greatly between site areas, non-local raw materials do appear to have been more common in the plaza area than other areas and local raw materials are more prevalent in the 1984 ravine (Fig. 6.1). This supports the idea that artifacts made from expensive non-local raw materials were treated differently than local raw materials by the people of Aztalan. Expensive materials were more likely to be curated and inexpensive local raw materials were more readily discarded as trash. The fact that smaller pieces of debitage were significantly non-local suggests that tools made from these materials were resharpened more often than non-local tools. Furthermore, the significant relationship between quality and debitage form may also reflect economizing behavior at Aztalan. A significantly higher frequency of heat treated artifacts in the plaza could also reflect this type of economizing behavior because after heat treating a raw material, it’s value has been increased, transforming it into a more expensive product. Therefore, it would be unsurprising that fewer heat treated artifacts would be treated as trash and discarded in a midden.
Temporal Analyses Interpretation

While a larger dataset from discrete Late Woodland contexts would be helpful to confirm these arguments, there still does appear to be some observable differences in the organization of chipped stone technology when data from Late Woodland and mixed contexts are compared. There is obviously a wider variety of raw material types represented in the mixed context materials than in Late Woodland contexts. There are 26 different types of raw material represented in mixed contexts and only 11 different types are present in Late Woodland contexts. While there is no real change in the proportion of local raw materials, there is an increase in non-local raw materials from only 10% of Late Woodland context raw materials to 23% in mixed contexts (Fig. 6.2). Small amounts of expensive, good quality, non-local raw materials such as Burlington chert and St. Genevieve chert are present in Late Woodland contexts. However, there appears to be an increase in access to different varieties of non-local raw materials from southern
regions associated with the presence of Middle Mississippian inhabitants at the site. Certainly, the fact that Mill Creek chert is only present in mixed contexts suggests that there was some kind of shift that took place at the site in the organization of chipped stone technology. Mill Creek hoes would have been brought to Aztalan with the intention that they would reliably help to keep the people fed and would also be used to help build a new Middle Mississippian community with the least risk of failure possible. Another trend in chipped stone tool production appears when the frequency of heat treatment is compared. While the relationship between heat treatment and period is negligible, it seems that heat treatment of raw materials was utilized more frequently in Late Woodland contexts than in mixed contexts and statistically, burned shatter was found significantly more in Late woodland contexts than mixed contexts. If there was an increase in access to good quality non-local raw materials, then heat treating would have been less necessary and time and energy saved could have been devoted to other tasks. Likewise, there appears to be an increase in artifacts that are cortex-free from Late Woodland to mixed contexts. This suggests that raw materials were more likely to be brought to Aztalan already reduced into tools or at least in a more easily transportable form. The flake-to-tool ratio for both mixed and Late Woodland contexts is 6:1 suggesting that the frequency of stone tool production and maintenance did not increase or decrease over time at the site. This further suggests that quantities of non-local materials were not brought into the site with the intention of increasing the volume of chipped stone tool production but were rather an attempt to efficiently maximize time elsewhere in society.
Comparative Analysis

Other studies have incorporated similar economic methods to analyze data from chipped stone artifacts at other late prehistoric sites in the Midwest (Jeske 1992a; 1992b; 2002; 2003; Sterner 2012; 2018; Park 2014; Wilson 2016). The following discussion presents comparative data from four sites in northern Illinois and southern Wisconsin including LaSalle County Home, Zimmerman, Washington Irving, and Crescent Bay Hunt Club.

The LaSalle County Home site, located on the Illinois river in northeastern Illinois, is a multicomponent site with evidence of Middle Woodland, Late Woodland and Upper Mississippian Langford occupations (Jeske 1992b; 2002; 2003). The Langford tradition is an Upper Mississippian ceramic tradition in northern Illinois. Typically, calibrated radiocarbon dates for Langford sites fall in the range of A.D. 1200-1440 (Jeske 1990; 1992a). Langford groups lived in large, semi-permanent villages, employing a “generalized hunting-gathering
economy focused on wetland resources” augmented by maize as a major dietary supplement (Jeske 1992a:473). In 1993, Dr. Robert Jeske led an undergraduate field school at the LaSalle site with the goal of systematic sampling of the site to obtain more subsistence information (Jeske 2002). Jeske analyzed 4,807 pieces of debitage and 62 chipped stone tools recovered from these excavations “yielding a 77:1 debitage to tool ratio” (Jeske 2000:95). Overall, Jeske characterized the lithic technological organization at the LaSalle County Home site as “following a highly curated pattern of tool manufacture, use and discard” that was based on the conservative use of locally available raw materials. In all, 99.94% of the debitage and 74% of the tools analyzed by Jeske were found to be made from locally available raw materials (Fig. 6.3). These locally available materials consisted of 84.3% varieties of Kankakee chert, other Silurian cherts and pebble cherts (Jeske 2002:95). The remaining 15.64% of local raw materials were low quality Colchester coal or exoshale, which is a type of petrified wood that outcrops approximately five kilometers from the site (Jeske 2002; Ferguson and Warren 1992). Non-local materials made up only .06% of the assemblage, consisting of 3 flakes of Wyandotte chert, a high quality raw material found in southern Indiana (Jeske 2002). Jeske reported that only 39% of the tools were made from good quality materials, 57% were fair and 4% poor quality, also that there was very little effort to increase the quality of raw materials with only 5% of tools showing any indication of heat treatment (Jeske 2002). When Jeske compared use of raw materials by earlier Woodland occupants to later Mississippian occupants, he found that Woodland occupants used a much larger proportion of non-local raw materials as well as a larger proportion of good quality materials (Jeske 2002). Energy input for tool manufacture was measured by observing the amount of cortex left on tool surfaces. Jeske found that tool manufacturers put a moderate to significant amount of energy into producing chipped stone tools
with 87% of the tools being cortex-free (Jeske 2002). Also, intensity of use was measured by the number of functional units. Tools were found to have been used extensively before being discarded. (Jeske 2002:113). When Jeske compared data from the 1993 excavations with data from an earlier Woodland occupation of the site he found that “Woodland occupants chose much better raw materials with 73% of materials coded as good in quality” (Jeske 2002:102).

The Zimmerman site is a multicomponent site located on the Illinois river, just five kilometers upstream from the LaSalle County Home site, that produced evidence of Woodland, Langford and historic occupations (Park 2004). Dr. SungWoo Park analyzed lithic artifacts from excavations at the Zimmermann site by Northwestern University from 1987 and 1991 to 1995 (Park 2004). Park compared lithic materials associated with a Langford occupation of the site with the a later protohistoric Fort Ancient occupation (Park 2014). In all, Park analyzed 4,822 pieces of debitage and 35 chipped stone tools (Park 2004:99). Of the 35 tools analyzed from Langford contexts, Park reported that 86% of the raw materials were produced from locally available raw materials and 14% were non-local (Park 2004). The flake-to-tool ratio from the Langford context materials was a high 138:1. Also, 67% of the tools he analyzed were cortex-free (Fig. 6.3). Surprisingly, Park found that statistical analysis showed there were no changes in the proportions of non-local and local raw materials or the quality of raw materials over time at the site (Park 2004). While he did notice a slight increase in the use of bipolar reduction and in the amount of cortex on debitage over time, Park concluded that “there was no large-scale shift in lithic technology consistent with a large-scale shift in subsistence economy” (Park 2004:155).

The Washington Irving site, is a single-component Langford village site located along the Fox river in northern Illinois (Jeske 1992, 2000; Wilson 2016). There are no good nearby sources of raw material however, there is “an abundant supply of cherty gravel located in glacially
derived till or outwash deposits...in the form of small, irregular cobbles and pebbles, usually weathered, containing many frost cracks and fossiliferous inclusions” (Jeske 1992a:473).

Stephen Wilson (2016) analyzed the chipped stone artifact assemblage from excavations conducted at the site during 1984 and 1985 field seasons. In all, Wilson analyzed 1,641 pieces of debitage and 101 chipped stone tools from the Washington Irving site (Wilson 2016). This suggests a flake-to-tool ratio of 16:1 however, Wilson points out that “as ½ inch mesh screens were used during excavation, the inclusion of size grade two pieces (8mm to 12.5mm) from flotation to the assemblage sampled in this thesis would result in a debitage-to-tool ratio at Washington Irving that is considerably higher” (Wilson 2016:112). Based on data from tabulation records from the excavations, Wilson reported that the actual flake-to-tool ratio for the assemblage is approximately 100:1 (Wilson 2016). Of the 101 tools, 74% were made from chert that is local to the site and only 5% were made from non-local chert. Also, only 4% of the tools in the assemblage were of good quality, 74% were fair and 22% were of poor quality (Wilson 2016). Additionally, most of the tools displayed no cortex (73%) and very few (27%) were heat treated (Wilson 2016) (Fig. 6.3).

The Crescent Bay Hunt Club Site is an Oneota site located on the northwestern shore of lake Koshkonong in southwestern Jefferson County, Wisconsin. Oneota tradition (A.D. 1100-1650) refers a late prehistoric culture characterized by shell-tempered pottery found throughout much of the Midwest (Overstreet 1998). Connected by the Rock and Crawfish rivers, Aztalan is approximately 15 miles upstream from Lake Koshkonong. Dr. Katherine Sterner analyzed 1,221 pieces of chipped stone debitage and 244 chipped stone tools excavated in 2004 by UWM field school students (Sterner 2012). Like at Aztalan, a low flake-to-tool ratio of just 5:1 suggests that lithic resources were used economically at Crescent Bay. Of the 244 tools Sterner analyzed, 3%
were of good quality, 86% were fair and 11% were of poor quality (Sterner 2012). Also, 60% of these tools were made from locally available raw materials and 19% were made from non-local raw materials (Sterner 2012). Most of the tools from Crescent bay displayed no cortex (72%) and were not heat treated (72.5%) (Fig. 6.3).

When data from these sites are compared to Aztalan, some broad trends appear. Langford sites in northern Illinois clearly have higher flake-to-tool ratios than sites in southeastern Wisconsin. This is likely due to differences in access to raw materials because of variation in the geologic make-up of the underlying bedrock in these areas, and the density of glacial deposits covering them. Future research into lithic technological behaviors in the Midwest during the late prehistoric period should explore comparisons between these sites further so that differences or similarities in energetically efficient behavior may become clearer.

Fig.6.3: Site comparison chart (note: Heat treatment data for Zimmermann unavailable)
Southeastern Wisconsin Late Woodland Comparative Analysis

Data from four Late Woodland sites in southeastern Wisconsin were compared to the data from this project. These sites include; the Luedtke site (47DO393), the Weisner III site (47DO399), the Elmwood Island site (47DO47) and the Bethesda Lutheran Home site (47JE201) (Hendrickson 1996; Salkin 1989; 1993; 2000) (Fig. 6.4). The Luedtke site is a Late Woodland site located in Dodge County, Wisconsin on the Rock river. Archaeological Consulting and Services conducted excavations at the site during 1982 and 1983 (Salkin 1993). Over 90% of the debitage recovered from the Luedtke site consisted of locally available Silurian chert and the remaining debitage consisted of small amounts of Galena chert, Prairie du Chien chert, Burlington chert, silicified sandstone, Cobden chert and quartz (Salkin 1993). The Weisner III site is located 150 meters from the Luedtke site is interpreted as a Late Woodland fortified village (Salkin 1993) (Fig 6.4). As would be expected the lithic assemblage from the Weisner III excavations closely resemble that of the neighboring Luedtke site with 98% consisting of locally available Silurian, Galena and Prairie du Chien cherts (Salkin 1993). The Elmwood Island site is situated on an island near the center of Fox Lake in Dodge county, Wisconsin (Fig 6.4). The site represents a Late Woodland village. The Elmwood Island excavations produced over 37,000 pieces of debitage (Salkin 1989). Over 96% of the raw materials recovered from the Elmwood Island site consisted of locally available Prairie du Chien chert, Rhyolite, Galena chert and Silurian chert (Salkin 1989). Finally, the Bethesda Lutheran Home site is located just 15 km northeast of Aztalan near Watertown, Wisconsin (Hendrickson 1996; Salkin 2000) (Fig. 6.4). Like Aztalan, the Bethesda Lutheran Home site harbors both Late Woodland and Middle
Mississippian components (Hendrickson 1996; Salkin 2000). Hendrickson (1996) reported that over 66% of the debitage recovered during excavations at the site consisted of locally available raw materials such as Silurian, Galena and Prairie du Chien cherts, and the remaining 44% consisted of 14% Burlington chert, 3% Moline chert, 15% unidentified material, two flakes of possible Barron county chert, and one flake of silicified sandstone, one flake of rhyolite and one flake of quartz. All these late Woodland sites, along with the Aztalan site, have been assigned to the Late Woodland Kekoskee phase (Salkin 2000).
Fig. 6.4: Map of Late Woodland sites examined
Tabulations of raw material types for the sites discussed above are listed in Table 6.5. Data in Table 6.5 was used to conduct a comparative analysis of the diversity of raw material composition in the sites listed in Table 6.5. Measures of diversity were originally developed in evolutionary ecology (Pielou 1977) where they continue to be popular today. These same diversity indices have also been used by archaeologists to model assemblage diversity in archaeological data sets including faunal, floral, ceramic, and lithic assemblages (Schott 2010). Use of these measures in lithic analysis has been controversial due to the potential effect of sample size on statistical results (see Beck 2008, Leonard and Jones 1989, Schott 2010 for a review of these issues). Nonetheless, analysis of diversity was suggested by Robert Jeske (personal communication) as an additional way to test the results of the conventional lithic analysis presented earlier. The approach used here was modeled after that presented by Edwards in his analysis of between site diversity of faunal assemblages from a number of southern Wisconsin Oneota sites (Edwards 2017).
Two tests, including the Shannon-Weiner Index and Simpson’s Index, were used to calculate heterogeneity, evenness and richness of raw material composition of lithic assemblages from the sites listed in Table 6.5. The following discussion is abstracted from Edwards.
and Jeske (personal communication 2018). Shannon H is a measure of the overall heterogeneity of the assemblage and is a combination of richness and evenness. The higher the H value, the richer the assemblage. The E value is obtained by dividing the Shannon Index by the natural log of the taxonomic richness and describes how evenly spread across the assemblage the various raw materials are. The higher the E, the more even the distribution. Simpson D is a measure of how diverse the assemblage is; it measures the same thing as H, only in a different way. D values always fall between 0 and 1, where 0 indicates infinite diversity and 1 no diversity. The inverse of Simpson D (1/D) is another measure of evenness with higher scores indicating more even distributions.

Results of these tests suggest that the Aztalan mixed assemblage is richer and more diverse than the other Late Woodland sites; something that might be expected as the result of Middle Mississippian presence at the site (Table 6.6). However, the analysis also suggests that the Aztalan Late Woodland component is more diverse than the other Late Woodland sites tested. This suggests that the Late Woodland inhabitants of Aztalan may have been involved in a wider network than the other Late Woodland groups in the tested sample. (Jeske, personal communication 2018). In sum, results of the diversity analysis support the results of the lithic analysis conducted for this thesis that suggest there are significant differences between the Late Woodland and mixed Late Woodland/Mississippian lithic assemblage at Aztalan.

Chapter 7:
Conclusions and Future Research

Conclusions

The first major goal of this thesis was to characterize a subset of the Aztalan lithic assemblage through an assemblage-based approach, with the intention of answering questions involving energetic efficiency and the role it played in the lithic economy at the site. The data shows that while there is no change in flake-to-tool ratios in Late Woodland and mixed contexts, there are efficient changes in other aspects of stone tool production that would allow more time to be allocated elsewhere in society. Analysis of the 1,397 chipped stone artifacts excavated by the University of Wisconsin-Milwaukee from the Aztalan site during the 1984, 2011 and 2013 field seasons show a pattern of efficient stone tool use and production as well as the economical use of raw materials. Flake-to-tool ratios for non-local raw materials are low and are high for local raw materials. Likewise, the flake-to-tool ratio for good quality raw materials is low, slightly higher for fair quality materials and even higher for poor quality raw materials. This suggests that tools made from expensive, good quality non-local materials were likely transported to the site as completed tools and were not formed on site. Intensity of tool use also shows that chipped stone tools were used efficiently at the site. Additionally, the use of bipolar reduction combined with the heat treatment of local raw materials suggests that raw materials were used resourcefully. Also, like most late prehistoric groups, the residents of Aztalan mostly relied on expediently made tools with restricted use of standardized tool forms. However, Middle Mississippian influence from the American Bottom brought with it chipped stone tools such as
Mill creek chert hoes and good quality raw materials such as St. Genevieve chert that was believed to reduce failure rates in subsistence efforts and eliminate some of the risk in building a new hybrid community. Overall, chipped stone technology at Aztalan is mostly reliant on the opportunistic use of locally available raw materials supplemented by the conservative use of good quality non-local raw materials from the Mississippi river valley. There is obviously a wider variety of raw material types represented in the mixed context materials than in Late Woodland contexts. Again, a larger sample size would help to verify whether these trends hold true.

Another goal was to analyze the data spatially. Statistically significant relationships were identified for heat treatment as well as raw material locality. In the plaza and the 1984 Ravine areas, heat treatment was present significantly more than it was absent. While in the Riverbank area, heat treatment is absent significantly more than it is present. A significant relationship was also observed between locality and site area. Local raw materials were found significantly more than non-local materials in the 1984 ravine while non-local materials were found significantly more than local raw materials in the riverbank area. This reflects economizing behavior because non-local raw materials are more expensive, and artifacts made with them would have been less frequently discarded in a midden. There was also a significant relationship between site area and morpho-function. Understandably, edge-only tools were found in the Plaza area significantly more than bifaces, because expedient tools would have been more often discarded or lost in domestic debris. Also, hoe chips were found significantly more in the riverbank area which would make sense given that hoe chips have no utility as a tool by themselves. While these results are somewhat difficult to interpret, they probably suggest more than anything that more data is required.
Finally, the last goal of the project was to test the expectation that with greater social complexity there will be a greater need to organize chipped stone technology efficiently (Jeske 2002). With the expectation that with the additional costs of time and energy associated with the introduction of Middle Mississippian culture, efficient adjustments would have been required to be made to the lithic economy of the site. I argue that the data from the chipped stone artifacts in the UWM Aztalan assemblage supports this expectation. The UWM lithic assemblage suggests that lithic technological organization changed over time. Statistical analysis of the data from this project shows that with increased Middle Mississippian interaction came increased access to non-local raw materials. Not only was there an increase in access to non-local raw materials, but raw materials were also heat treated significantly less over time. Additionally, the results of this project suggest that the Late Woodland occupation at Aztalan may have already had access to a wider variety of raw materials than other Late Woodland groups in southeastern Wisconsin. These observable shifts in how lithic technology was organized at the Aztalan site support the idea that residents were involved in complex interpersonal relationships and had access to far reaching trade networks associated with Middle Mississippian society. In an area where there is no access to locally available, good quality raw materials, Aztalan inhabitants responded by importing chipped stone tools and raw materials so less time would be spent attempting to improve poor quality raw materials through heat treating. Whether this shift was a response to changing subsistence strategies, resource depletion or rapid population growth is unknown. Nevertheless, the inhabitants of Aztalan appear to have been attempting to efficiently maximize returns on chipped stone tool production and raw material utilization.
**Future Prospects**

Future excavations at the Aztalan site should put locating potentially isolated Late Woodland deposits high on their list of goals, but there are additional lithic analyses that can be done in the meantime to produce a more robust data set. According to Kurt Sampson, “the MPM Aztalan collection contains a significant amount of lithic debitage from the S.A. Barrett excavations that could be analyzed to help further understand lithic reduction and procurement strategies at this site” (Sampson 2008:135). Also, during 1962, 1964, 1967, and 1968, excavations were conducted by the Wisconsin Historical Society under the direction of Joan Freeman (Clauter and Richards 2009; Zych 2013). Freeman concentrated her efforts on recovering additional information concerning house types and on the archaeological documentation of the northeast platform mound. These excavations resulted in discovery of nine additional houses as well as their associated features (Clauter and Richards 2009; Zych 2013). Additionally, the remains of the northeast mound were located along with evidence of a large, open structure which likely topped the mound at one time (Freeman 1986; Clauter and Richards 2009). To date, much of the lithic materials collected during these excavations remain unanalyzed and unreported (Clauter and Richards 2009). Another legacy data set consists of materials recovered by the WAS during the 1950s. These materials are currently curated at University of Wisconsin. Finally, materials excavated by the 2013 MSU field school are now curated in UWM’s Archaeological Research Laboratory and would form a useful addition to the present research. Another potential avenue of analysis is in micro-wear and use-wear analysis. These types of analyses can provide extremely valuable data because “morpho-functional typologies are of limited utility when examining late prehistoric assemblages where large numbers of tools do not fit into any formal category” (Sterner 2012:106). High-power analyses,
which examines artifacts at 200-300x magnification using a binocular incident-light metallurgical microscope, can locate certain polishes and striations which can reveal information such as direction of use, and the material the tool was used on (Sterner 2012).
